#### Abstract

We study mean-variance hedging under portfolio constraints in a general semimartingale model. The constraints are formulated via predictable correspondences, meaning that the trading strategy is restricted to lie in a closed convex set which may depend on the state and time in a predictable way. To obtain the existence of a solution, we first establish the closedness in $L^{2}$ of the space of all gains from trade (i.e., the terminal values of stochastic integrals with respect to the price process of the underlying assets). This is a first main contribution which enables us to tackle the problem in a systematic and unified way. In addition, using the closedness allows us to explain and generalise in a systematic way the convex duality results obtained previously by other authors via ad hoc methods in specific frameworks.

Key words: mean-variance hedging, constraints, stochastic integrals, convex duality (to appear in the Applied Probability journals)

## 1 Introduction

Mean-variance hedging and mean-variance portfolio selection are two classical problems in finance. The latter is also called Markowitz problem and involves finding a trading strategy whose resulting final wealth has an optimal risk-reward profile, where reward and risk are measured via mean and variance. Understanding and solving this problem is vastly simplified by a good knowledge about the general mean-variance or quadratic hedging problem. We study this in a general semimartingale financial market with general convex constraints on strategies.

In more mathematical terms, let $S=\left(S_{t}\right)_{0 \leq t \leq T}$ be an $\mathbb{R}^{d}$-valued semimartingale modelling the discounted prices of $d$ risky assets. A self-financing trading strategy is described by its initial wealth $x \in \mathbb{R}$ and an $\mathbb{R}^{d}$-valued predictable process $\vartheta=\left(\vartheta_{t}\right)_{0 \leq t \leq T}$ describing the numbers of shares held dynamically over time. Its resulting final wealth is

$$
V_{T}(x, \vartheta):=x+\int_{0}^{T} \vartheta_{s} d S_{s}=: x+G_{T}(\vartheta),
$$

and if the $\mathcal{F}_{T}$-measurable random variable $H$ gives the time- $T$ payoff of a financial product, mean-variance hedging for $H$ is to solve the (linear-quadratic control) problem to

$$
\text { minimise } E\left[\left|H-x-G_{T}(\vartheta)\right|^{2}\right]
$$

either over $\vartheta \in \Theta_{S}(C)$ for fixed $x$ or over $(x, \vartheta) \in \mathbb{R} \times \Theta_{S}(C)$. The space $\Theta_{S}(C)$ of "allowed" integrands of course imposes a square-integrability condition on the stochastic integral process $\int \vartheta d S$, and the argument $C$ in brackets indicates that we have trading constraints in the sense that $\vartheta_{t}(\omega)$ must lie in a convex closed subset $C(\omega, t)$ of $\mathbb{R}^{d}$. This can depend on $\omega$ and $t$ in a predictable way, as made precise later, and it is worth pointing out that the $C(\omega, t)$ need not be cones in general. One strength of our contribution is that the above setup is essentially the most general formulation for mean-variance hedging under constraints. Under very weak local square-integrability and no-arbitragetype assumptions on $S$, we give in Theorem 3.12 a necessary and sufficient condition (jointly on $S$ and $C$ ) for the space $G_{T}\left(\Theta_{S}(C)\right.$ ) to be closed in $L^{2}(P)$. This allows us to prove easily in Theorem 4.1 the existence of a solution to the mean-variance hedging problem for any $H \in L^{2}(P)$. To obtain more information on the structure of this solution, we then use convex duality tools. We introduce a dual problem whose variables and objective function both involve the constraints $C$ through their support function. We then prove in Theorems 5.7 and 5.13 the existence of a solution to the dual problem, show how it is related to the solution of the primal problem, and give properties of the corresponding (primal and dual) value functions. There are two sets of results because we give two formulations - one in terms of static, the other in terms of dynamic variables.

Conceptually and result-wise, our duality approach is analogous to the classical convex duality techniques familiar from utility maximisation problems; see the work by Cvitanić and Karatzas [5], Kramkov and Schachermayer [18] and Karatzas and Žitković [17].

However, the mathematics are somewhat different since our "quadratic random utility" $U(x, \omega)=-\frac{1}{2}|x-H(\omega)|^{2}$ is not increasing in $x$ and the duality is taken in a different space. A fairly close precursor of our work is due to Labbé and Heunis [19] who studied the same problem when $S$ is given by a complete Itô process model and the constraints do not depend on $\omega$ and $t$. Their duality is very similar to parts of our Theorem 5.13, but their formulations and in particular their proofs strongly depend on the availability and use of Itô's representation theorem. We do not need that at all, since $S$ and the underlying filtration $\mathbb{F}$ are general in our setting.

The paper is structured as follows. Section 2 contains a precise problem formulation, including basic results on correspondences that we use for the modelling of constraints. Section 3 contains the central closedness result for $G_{T}\left(\Theta_{S}(C)\right)$, and Section 4 uses this to prove existence of a solution to the mean-variance hedging problem under constraints. Finally, Section 5 presents the duality results. We first give a careful motivation for the way the dual problem is set up, both for static and dynamic variables. Then we prove the main duality theorems in those two settings, and we close the section with more detailed comments on and comparison to the literature.

## 2 Formulation of the problem

Let $(\Omega, \mathcal{F}, P)$ be a probability space with a filtration $\mathbb{F}=\left(\mathcal{F}_{t}\right)_{0 \leq t \leq T}$ satisfying the usual conditions of completeness and right-continuity, where $T>0$ is a fixed and finite time horizon. Hence we can and do choose for every local $P$-martingale a version whose trajectories are right-continuous with left limits ( RCLL). For all unexplained notions concerning stochastic integration, we refer to Protter [24].

We consider a financial market consisting of one riskless asset, whose (discounted) price is 1 , and $d$ risky assets described by an $\mathbb{R}^{d}$-valued semimartingale $S$. We denote by $\mathcal{H}^{2}(P)$ the Banach space of all square-integrable semimartingales, i.e. special semimartingales $Y$ with canonical decomposition $Y=Y_{0}+M^{Y}+A^{Y}$, where $M^{Y}$ is a square-integrable martingale $Y$ null at zero, $M^{Y} \in \mathcal{M}_{0}^{2}(P)$, and $A^{Y}$ is a predictable finite variation RCLL process null at zero, such that

$$
\|Y\|_{\mathcal{H}^{2}(P)}:=\left\|Y_{0}\right\|_{L^{2}(P)}+\left\|\left(\left[M^{Y}\right]_{T}\right)^{\frac{1}{2}}\right\|_{L^{2}(P)}+\left\|\int_{0}^{T}\left|d A_{s}^{Y}\right|\right\|_{L^{2}(P)}<\infty .
$$

Note that $\mathcal{H}_{\text {loc }}^{2}(P)$ coincides with the semimartingale space $\mathcal{S}_{\text {loc }}^{2}(P)$. We suppose that $S$ is a locally square-integrable semimartingale, for short $S \in \mathcal{H}_{\mathrm{loc}}^{2}(P)$, with canonical decomposition $S=S_{0}+M+A$. Then there exists a predictable increasing RCLL process $B$, e.g. $B=\sum_{i=1}^{d}\left(\left\langle M^{i}\right\rangle+\int\left|d A^{i}\right|\right)$, with $\left\langle M^{i}, M^{j}\right\rangle \ll B$ and $A^{i} \ll B$ for $i, j=1, \ldots, d$. We define an $\mathbb{R}^{d \times d}$-valued predictable process $c^{M}$ and an $\mathbb{R}^{d}$-valued predictable process $a$ by $\left(c^{M}\right)^{i j}=\frac{d\left\langle M^{i}, M^{j}\right\rangle}{d B}$ and $a^{i}=\frac{d A^{i}}{d B}$. We set $\bar{\Omega}:=\Omega \times[0, T], P_{B}:=P \otimes B$ and view $\mathbb{R}^{d}$-valued predictable processes as $\mathcal{P}$-measurable random variables, i.e. elements of $\mathcal{L}^{0}\left(\bar{\Omega}, \mathcal{P} ; \mathbb{R}^{d}\right)$.

For trading strategies, we take

$$
\Theta:=\Theta_{S}:=\left\{\vartheta \in \mathcal{L}(S) \mid \int \vartheta d S \in \mathcal{H}^{2}(P)\right\},
$$

where $\mathcal{L}(Y)$ denotes the space of all $\mathbb{R}^{d}$-valued, $Y$-integrable, predictable processes for a semimartingale $Y$. Note that we work with processes without identifying $\vartheta$ and $\vartheta^{\prime}$ when $\int \vartheta d S=\int \vartheta^{\prime} d S$; hence we write $\mathcal{L}(S)$, not $L(S)$. By the uniqueness of the canonical decomposition, we have that $\Theta_{S}=\mathcal{L}^{2}(M) \cap \mathcal{L}^{2}(A)$ with

$$
\begin{aligned}
\mathcal{L}^{2}(M) & :=\left\{\vartheta \in \mathcal{L}^{0}\left(\bar{\Omega}, \mathcal{P} ; \mathbb{R}^{d}\right) \mid\|\vartheta\|_{\mathcal{L}^{2}(M)}:=\left(E\left[\int_{0}^{T} \vartheta_{s}^{\top} c_{s}^{M} \vartheta_{s} d B_{s}\right]\right)^{\frac{1}{2}}<\infty\right\} \\
\mathcal{L}^{2}(A) & :=\left\{\vartheta \in \mathcal{L}^{0}\left(\bar{\Omega}, \mathcal{P} ; \mathbb{R}^{d}\right) \mid\|\vartheta\|_{\mathcal{L}^{2}(A)}:=\left(E\left[\left(\int_{0}^{T}\left|\vartheta_{s}^{\top} a_{s}\right| d B_{s}\right)^{2}\right]\right)^{\frac{1}{2}}<\infty\right\} .
\end{aligned}
$$

The wealth process generated up to time $t \in[0, T]$ by a self-financing trading strategy $\vartheta$ with initial capital $x \in \mathbb{R}$ is

$$
V_{t}(x, \vartheta):=x+\int_{0}^{t} \vartheta_{s} d S_{s}=: x+G_{t}(\vartheta),
$$

where the process $G(\vartheta)$ denotes the cumulative gains from trading. The set of all outcomes of self-financing trading strategies with zero initial wealth is

$$
G_{T}\left(\Theta_{S}\right)=\left\{G_{T}(\vartheta) \mid \vartheta \in \Theta_{S}\right\},
$$

and the set of attainable payoffs is

$$
\mathcal{A}\left(\Theta_{S}\right)=\mathbb{R}+G_{T}\left(\Theta_{S}\right)
$$

In contrast to strategies, we identify here final wealths that are equal $P$-a.s. Due to the definition of $\Theta_{S}$, the sets $G_{T}\left(\Theta_{S}\right)$ and $\mathcal{A}\left(\Theta_{S}\right)$ are thus linear subspaces of $L^{2}(P)$ by the following result.

Proposition 2.1. Let $Y$ be a semimartingale in $\mathcal{H}^{2}(P)$ and $Y_{t}^{*}:=\sup _{0 \leq s \leq t}\left|Y_{s}\right|$. Then

$$
E\left[\left(Y_{T}^{*}\right)^{2}\right] \leq 8\|Y\|_{\mathcal{H}^{2}(P)}^{2}
$$

Proof. See Theorem IV. 5 in [24].
A square-integrable $\mathcal{F}_{T}$-measurable random variable $H$ is called a contingent claim. We assume that an investor wants to hedge a contingent claim by means of a self-financing trading strategy. However, since the market is usually incomplete, perfect replication of the contingent claim, in the sense that $H=V_{T}(x, \vartheta) P$-a.s. for some $x$ and $\vartheta$, is in general impossible. So the investor wants to optimise the hedging performance of his trading strategy according to some criterion. One possible choice, especially when the investor
simultaneously considers buying or selling $H$, is the minimisation of the mean squared hedging error, which leads to the approximation problem

$$
E\left[\left|H-x-\int_{0}^{T} \vartheta_{s} d S_{s}\right|^{2}\right]=\min _{(x, \vartheta) \in \mathbb{R} \times \Theta_{S}}!
$$

For a fixed initial capital $x \in \mathbb{R}$, one obtains the problem of mean-variance hedging, i.e.

$$
E\left[\left|H-x-\int_{0}^{T} \vartheta_{s} d S_{s}\right|^{2}\right]=\min _{\vartheta \in \Theta_{S}}!
$$

Mathematically, this amounts to projecting $H-x$ onto $G_{T}\left(\Theta_{S}\right)$ or $H$ onto $\mathcal{A}\left(\Theta_{S}\right)$. Therefore a solution for every $H \in L^{2}(P)$ exists if and only if $G_{T}\left(\Theta_{S}\right)$ and $\mathcal{A}\left(\Theta_{S}\right)$ are closed in $L^{2}(P)$. Note that both problems are naturally studied in $L^{2}(P)$ rather than $\mathcal{L}^{2}(P)$.

Before we introduce the mean-variance hedging problem under trading constraints, we make the following simple observation. In the unconstrained case, when $G_{T}\left(\Theta_{S}\right)$ and $\mathcal{A}\left(\Theta_{S}\right)$ are closed linear subspaces, the problem admits a unique solution by elementary Hilbert space arguments. Under trading constraints, this is still true if the subsets in which we want to find the best approximation are closed and convex subsets of $L^{2}(P)$. Despite its simplicity, this observation is very useful. We shall see that mean-variance hedging problems can be embedded into this framework even under the additional constraint that the trading strategy only takes values in a closed convex set, which is allowed to depend on the state $\omega$ and time $t$ in a predictable way. This allows us to treat these problems in a systematic and unified way.

To model "predictable trading constraints", we formulate them via predictable correspondences. This idea is analogous to [15], where it is used to study the existence of the numéraire portfolio under predictable convex constraints.
Definition 2.2. A mapping $C: \bar{\Omega} \rightarrow 2^{\mathbb{R}^{d}}$ is called a correspondence. We say that a correspondence $C$ is predictable if $C^{-1}(F)=\{(\omega, t) \mid C(\omega, t) \cap F \neq \emptyset\}$ is a predictable set (i.e. in $\mathcal{P}$ ) for all closed $F \subseteq \mathbb{R}^{d}$. The domain $\operatorname{dom}(C)$ of a correspondence is given by $\operatorname{dom}(C)=\{(\omega, t) \mid C(\omega, t) \neq \emptyset\}$. A (predictable) selector of a (predictable) correspondence $C$ is a (predictable) process $\psi$ with $\psi(\omega, t) \in C(\omega, t)$ for all $(\omega, t) \in \operatorname{dom}(C)$.

For convenience, we recall some results on predictable correspondences which ensure the existence of predictable selectors in all situations relevant for us.

Proposition 2.3 (Castaing). For a correspondence $C: \bar{\Omega} \rightarrow 2^{\mathbb{R}^{d}}$ with closed values, the following are equivalent:

1) $C$ is predictable.
2) $\operatorname{dom}(C)$ is predictable and there exists $a$ Castaing representation of $C$, i.e. a sequence $\left(\psi^{n}\right)$ of predictable selectors of $C$ such that

$$
C(\omega, t)=\overline{\left\{\psi^{1}(\omega, t), \psi^{2}(\omega, t), \ldots\right\}} \quad \text { for each }(\omega, t) \in \operatorname{dom}(C) .
$$

In particular, every closed-valued predictable $C$ admits a predictable selector $\psi$. Proof. See Corollary 18.14 in [1] or Theorem 1B in [26].
Proposition 2.4. Let $C: \bar{\Omega} \rightarrow 2^{\mathbb{R}^{d}}$ be a predictable correspondence with closed values and $f: \bar{\Omega} \times \mathbb{R}^{m} \rightarrow \mathbb{R}^{d}$ and $g: \bar{\Omega} \times \mathbb{R}^{d} \rightarrow \mathbb{R}^{m}$ Carathéodory functions, which means that $f(\omega, t, y)$ and $g(\omega, t, x)$ are predictable with respect to $(\omega, t)$ and continuous in $y$ and $x$. Then the mappings $C^{\prime}$ and $C^{\prime \prime}$ given by $C^{\prime}(\omega, t)=\left\{y \in \mathbb{R}^{m} \mid f(\omega, t, y) \in C(\omega, t)\right\}$ and $C^{\prime \prime}(\omega, t)=\overline{\{g(\omega, t, x) \mid x \in C(\omega, t)\}}$ are predictable correspondences (from $\bar{\Omega}$ to $2^{\mathbb{R}^{m}}$ ) with closed values.
Proof. See Corollaries 1P and 1Q in [26].
Proposition 2.5. Let $C^{n}: \bar{\Omega} \rightarrow 2^{\mathbb{R}^{d}}$ for each $n \in \mathbb{N}$ be a predictable correspondence with closed values and define the correspondences $C^{\prime}$ and $C^{\prime \prime}$ by $C^{\prime}(\omega, t)=\bigcap_{n \in \mathbb{N}} C^{n}(\omega, t)$ and $C^{\prime \prime}(\omega, t)=\bigcup_{n \in \mathbb{N}} C^{n}(\omega, t)$. Then $C^{\prime}$ and $C^{\prime \prime}$ are predictable and $C^{\prime}$ is closed-valued.
Proof. See Theorem 1M in [26] and Lemma 18.4 in [1].
For a predictable correspondence $C: \bar{\Omega} \rightarrow 2^{\mathbb{R}^{d}} \backslash\{\emptyset\}$, we denote by

$$
\mathcal{C}:=\mathcal{C}^{S}:=\{\psi \in \mathcal{L}(S) \mid \psi(\omega, t) \in C(\omega, t) \text { for all }(\omega, t) \in \bar{\Omega}\}
$$

the set of $C$-valued or $C$-constrained integrands for $S$ and by

$$
\Theta_{S}(C)=\Theta_{S} \cap \mathcal{C}=\left\{\vartheta \in \Theta_{S} \mid \vartheta(\omega, t) \in C(\omega, t) \text { for all }(\omega, t) \in \bar{\Omega}\right\}
$$

the set of all $C$-constrained trading strategies. With this formulation, the set of all outcomes of $C$-constrained self-financing trading strategies with zero initial wealth is

$$
G_{T}\left(\Theta_{S}(C)\right)=\left\{G_{T}(\vartheta) \mid \vartheta \in \Theta_{S}(C)\right\},
$$

and the set of payoffs that are attainable with $C$-constrained trading strategies is

$$
\mathcal{A}\left(\Theta_{S}(C)\right)=\mathbb{R}+G_{T}\left(\Theta_{S}(C)\right)
$$

Note that one can for example model prohibition of short-selling or rectangular constraints in this formulation; see Examples 4.1 in Section 5.4 of [16]. The mean-variance hedging problem under trading constraints is now formulated as

$$
E\left[\left|H-x-\int_{0}^{T} \vartheta_{s} d S_{s}\right|^{2}\right]=\min _{\vartheta \in \Theta_{S}(C)}!
$$

for a fixed initial capital $x \in \mathbb{R}$, and we also study

$$
E\left[\left|H-x-\int_{0}^{T} \vartheta_{s} d S_{s}\right|^{2}\right]=\min _{(x, \vartheta) \in \mathbb{R} \times \Theta_{S}(C)}!
$$

when including the initial capital into the approximation problem. As already explained above, these problems admit solutions if $G_{T}\left(\Theta_{S}(C)\right)$ and $\mathcal{A}\left(\Theta_{S}(C)\right)$ are closed and convex subsets of $L^{2}(P)$. By the convexity of $C$, the convexity of $G_{T}\left(\Theta_{S}(C)\right)$ and $\mathcal{A}\left(\Theta_{S}(C)\right)$ immediately follows. The closedness will be established in the next section.

## 3 The closedness of $G_{T}\left(\Theta_{S}(C)\right)$ and $\mathcal{A}\left(\Theta_{S}(C)\right)$

In this section, we show that the set of all outcomes of $C$-constrained self-financing trading strategies with zero initial wealth and the set of all payoffs that are attainable with $C$-constrained trading strategies are both closed in $L^{2}(P)$. To that end, we use the concept of $\mathcal{E}$-martingales, which was introduced and developed by Choulli, Krawczyk and Stricker in [4] to deduce the closedness of the analogous subspaces in the unconstrained case. For easy reference, we start by briefly recalling some definitions and results.

For a semimartingale $Y$, we denote its stochastic exponential by $\mathcal{E}(Y)$. Throughout this paper, let $N$ be a fixed local $P$-martingale starting at zero. For any stopping time $\tau$, we denote the process $Y$ stopped at $\tau$ by $Y^{\tau}$ and the process $Y$ started at $\tau$ by ${ }^{\tau} Y=Y-Y^{\tau}$, but we set ${ }^{\tau} \mathcal{E}={ }^{\tau} \mathcal{E}(N)=\mathcal{E}\left(N-N^{\tau}\right)$. So for the stochastic exponential, ${ }^{\tau} \mathcal{E}(N)$ denotes a multiplicative rather than an additive restarting. Since $N$ is $P$-a.s. RCLL, it has at most a finite number of jumps with $\Delta N=-1$, and moreover each ${ }^{\tau} \mathcal{E}(N)$ can jump to zero at most once. Therefore we can define an increasing sequence of stopping times by $\widehat{T}_{0}=0$ and $\widehat{T}_{n+1}=\inf \left\{t>\left.\widehat{T}_{n}\right|^{T_{n}} \mathcal{E}(N)_{t}=0\right\} \wedge T=\inf \left\{t>\widehat{T}_{n} \mid \Delta N_{t}=-1\right\} \wedge T$, and $\left(\widehat{T}_{n}\right)$ tends to $T$ stationarily; this follows from the representation of the stochastic exponential in Theorem II. 37 in [24].

Definition 3.1. An adapted RCLL process $Y$ is an $\mathcal{E}$-local martingale if the product of $\widehat{T}_{n} Y$ and $\widehat{T}_{n} \mathcal{E}$ is a local $P$-martingale for any $n \in \mathbb{N}$. It is an $\mathcal{E}$-martingale if for any $n \in \mathbb{N}$, we have $E\left[\left|Y_{\widehat{T}_{n}}^{\widehat{T}_{n}} \mathcal{E}_{\widehat{T}_{n+1}}\right|\right]<\infty$ and the above product is a (true) $P$-martingale.

The next two propositions, which are Corollaries 3.16 and 3.17 in [4], give some information about the structure of $\mathcal{E}$-martingales.

Proposition 3.2. Let $Y$ be a special semimartingale and $Y=Y_{0}+M^{Y}+A^{Y}$ its canonical decomposition. Then $Y$ is an $\mathcal{E}$-local martingale if and only if $\left[M^{Y}, N\right]$ is locally $P$-integrable and $A^{Y}=-\left\langle M^{Y}, N\right\rangle$.

Proposition 3.3. A semimartingale $Y=Y_{0}+M^{Y}-\left\langle M^{Y}, N\right\rangle$ with $E\left[Y_{T}^{*}\left(\widehat{T}_{n} \mathcal{E}\right)_{T}^{*}\right]<\infty$ for any $n \in \mathbb{N}$ is an $\mathcal{E}$-martingale.

We also need the following definitions.
Definition 3.4. We say that $\mathcal{E}$ is regular if ${\widehat{T_{n}}}^{\mathcal{E}}$ is a $P$-martingale for any $n$.
Definition 3.5. We say that $\mathcal{E}$ satisfies the reverse Hölder inequality $R_{2}(P)$ if there exists a constant $c \geq 1$ such that $E\left[\left|{ }^{t} \mathcal{E}_{T}\right|^{2} \mid \mathcal{F}_{t}\right] \leq c$ for any $t$.

The next proposition is a partial statement of Proposition 3.9 in [4].
Proposition 3.6. Assume that $\mathcal{E}$ satisfies $R_{2}(P)$. Then $\mathcal{E}$ is regular if and only if ${ }^{\tau} \mathcal{E}$ is a $P$-martingale for any stopping time $\tau$, and in that case, ${ }^{\tau} \mathcal{E}$ is a $P$-square-integrable $P$-martingale.

Finally, a combination of Theorem 4.9 in [4] and Proposition 2.1 gives the following equivalence of norms.

Proposition 3.7. Assume that $\mathcal{E}$ is regular and satisfies $R_{2}(P)$. Then there exists a constant $c$ such that

$$
\frac{1}{c}\|Y\|_{\mathcal{H}^{2}(P)} \leq\left\|Y_{T}\right\|_{L^{2}(P)} \leq c\|Y\|_{\mathcal{H}^{2}(P)}
$$

for every $\mathcal{E}$-martingale $Y$. We write this for short as $\|Y\|_{\mathcal{H}^{2}(P)} \sim\left\|Y_{T}\right\|_{L^{2}(P)}$.
Note that when ${ }^{0} \mathcal{E}(N)$ is a strictly positive $P$-martingale, the definition of an $\mathcal{E}$-local martingale coincides with the notion of a local martingale under the measure $Q$ defined by $d Q={ }^{0} \mathcal{E}(N)_{T} d P$. This will be called the classical case.

As explained in the previous section, we consider a possibly incomplete financial market composed of one riskless asset, whose price is 1 , and $d$ risky assets described by an $\mathbb{R}^{d}$-valued semimartingale $S \in \mathcal{H}_{\text {loc }}^{2}(P)$ with canonical decomposition $S=S_{0}+M+A$. We suppose that there exists $N \in \mathcal{M}_{0, \text { loc }}(P)$ such that $S$ is an $\mathcal{E}$-local martingale. By Proposition 3.2, this implies that $\langle M, N\rangle$ exists and $A=-\langle M, N\rangle$. Moreover, we assume that $\mathcal{E}(N)$ satisfies $R_{2}(P)$, which gives that $N$ is locally $P$-square integrable and in $b m o_{2}$, i.e. there exists a constant $c>0$ such that $E\left[\langle N\rangle_{T}-\langle N\rangle_{t} \mid \mathcal{F}_{t}\right] \leq c$ for all $t \in[0, T]$; see Proposition 3.10 in [4]. An application of the Kunita-Watanabe decomposition yields $N=-\int \lambda d M+L$ with $\lambda \in \mathcal{L}^{2}(M)$ and $L \in \mathcal{M}_{0}^{2}(P)$ strongly $P$-orthogonal to $M$, and hence $S$ satisfies the structure condition (SC), i.e.

$$
S=S_{0}+M+\int d\langle M\rangle \lambda .
$$

Since $N$ is in $b \mathrm{mo}_{2}, \int \lambda d M$ is also in $b m o_{2}$, which implies by Theorem 3.3 in [9] the inequality $D_{2}(P)$, i.e. there exists a constant $c>0$ such that $\|\vartheta\|_{\mathcal{L}^{2}(A)} \leq c\|\vartheta\|_{\mathcal{L}^{2}(M)}$ for all $\vartheta \in \mathcal{L}^{2}(M)$. As a consequence, we have $\Theta_{S}=\mathcal{L}^{2}(M)$. To motivate the closedness proof under trading constraints, we give below the argument for the unconstrained case, which is due to Choulli, Krawczyk and Stricker; see Theorem 5.2 in [4].

Proposition 3.8. Assume that $\mathcal{E}=\mathcal{E}(N)$ is regular and satisfies $R_{2}(P)$, and that $S \in \mathcal{H}_{\mathrm{loc}}^{2}(P)$ is an $\mathcal{E}$-local martingale. Then the following hold:

1) For each $\sigma$-field $\mathcal{B}_{0} \subseteq \mathcal{F}_{0}$ and each $Y_{0} \in L^{2}\left(\mathcal{B}_{0}\right)$, the process $Y_{0}+\int \vartheta d S \in \mathcal{H}^{2}(P)$ is an $\mathcal{E}$-martingale.
2) The spaces $G_{T}\left(\Theta_{S}\right), \mathcal{A}\left(\Theta_{S}\right)$ and $L^{2}\left(\mathcal{B}_{0}\right)+G_{T}\left(\Theta_{S}\right)$, for any $\sigma$-field $\mathcal{B}_{0} \subseteq \mathcal{F}_{0}$, are closed in $L^{2}(P)$.

Proof. 1) The stochastic integral $\int \vartheta d S$ is for each $\vartheta \in \Theta_{S}$ a special semimartingale in $\mathcal{H}^{2}(P)$ with canonical decomposition $\int \vartheta d S=\int \vartheta d M+\int \vartheta d A$. Since $S$ is an $\mathcal{E}$-local
martingale, we have $A=-\langle M, N\rangle$ by Proposition 3.2; so $\int \vartheta d A=-\left\langle\int \vartheta d M, N\right\rangle$ and therefore $\int \vartheta d S$ is an $\mathcal{E}$-local martingale again by Proposition 3.2. Since $\mathcal{E}$ is regular and satisfies $R_{2}(P)$, Proposition 3.6 states that ${ }^{\tau} \mathcal{E}$ is a square-integrable martingale for each stopping time $\tau$. By Doob's inequality and Proposition 2.1, $\left\{{ }^{\tau} \mathcal{E}\right\}_{T}^{*}$ and $\{G(\vartheta)\}_{T}^{*}$ are in $L^{2}(P)$ so that $\{G(\vartheta)\}_{T}^{*}\left\{{ }^{\tau} \mathcal{E}\right\}_{T}^{*}$ is in $L^{1}(P)$ for every stopping time $\tau$. Proposition 3.3 now implies that $G(\vartheta)$ is an $\mathcal{E}$-martingale. Replacing $G(\vartheta)$ by $Y_{0}$ shows in the same way that the constant process $Y_{0}$ is an $\mathcal{E}$-martingale for any $Y_{0} \in L^{2}\left(\mathcal{B}_{0}\right)$, and hence so is $Y_{0}+G(\vartheta)$.
2) Let $\left(Y_{0}^{n}+G_{T}\left(\vartheta^{n}\right)\right)$ be a sequence in $L^{2}\left(\mathcal{B}_{0}\right)+G_{T}\left(\Theta_{S}\right)$ converging to $H$ in $L^{2}(P)$. By part 1), each $Y_{0}^{n}+G\left(\vartheta^{n}\right)$ is an $\mathcal{E}$-martingale and therefore the sequence $\left(Y_{0}^{n}+G\left(\vartheta^{n}\right)\right.$ ) is a Cauchy sequence in the Banach space $\mathcal{H}^{2}(P)$ by Proposition 3.7, hence convergent to some $Y \in \mathcal{H}^{2}(P)$ which satisfies $Y_{T}=H$. Since the space (of processes) $Y_{0}+G\left(\Theta_{S}\right)$ is closed in $\mathcal{H}^{2}(P)$ (either by the construction of the stochastic integral as in Section IV. 2 in [24] or by Theorem V. 4 in [20]), there exists some $\vartheta \in \Theta_{S}$ with $Y=Y_{0}+G(\vartheta)$, and therefore $L^{2}\left(\mathcal{B}_{0}\right)+G_{T}\left(\Theta_{S}\right)$ is closed in $L^{2}(P)$. Choosing above $\mathcal{B}_{0}=\{\emptyset, \Omega\}$ and $Y_{0}^{n}=0$ for all $n \in \mathbb{N}$ then implies the closedness of $\mathcal{A}\left(\Theta_{S}\right)$ and $G_{T}\left(\Theta_{S}\right)$ in $L^{2}(P)$, which completes the proof.

Remark 3.9. Assuming that there exists $N \in \mathcal{M}_{0, \text { loc }}(P)$ such that $\mathcal{E}(N)$ is regular and $P$-square-integrable and such that $S$ is an $\mathcal{E}$-local martingale implies the weak no-arbitrage condition that $G_{T}\left(\Theta_{S}\right)$ admits no approximate profits in $L^{2}$; this means that $1 \notin \overline{G_{T}\left(\Theta_{S}\right)}$, where ${ }^{-}$denotes the closure in $L^{2}(P)$. See Section 4 in [27].

To obtain the closedness under constraints, we observe the following. If $\left(Y_{0}^{n}+G_{T}\left(\vartheta^{n}\right)\right)$ is a sequence in $L^{2}\left(\mathcal{B}_{0}\right)+G_{T}\left(\Theta_{S}(C)\right)$ converging to some $H$ in $L^{2}(P)$, then there exist under the assumptions of Proposition 3.8 some $Y_{0} \in L^{2}\left(\mathcal{B}_{0}\right)$ and some $\vartheta \in \Theta_{S}$ such that $Y_{0}+G_{T}(\vartheta)=H$ and $\left(Y_{0}^{n}+G\left(\vartheta^{n}\right)\right)$ converges to $Y_{0}+G(\vartheta)$ even in $\mathcal{H}^{2}(P)$. The question is then whether $\vartheta$ can be chosen to be $C$-valued. In general (even if $S$ is a martingale), the answer is negative, as a simple counterexample in Section 3 of [7] illustrates. The reason behind this is that the linear dependence of the different components of $S$ can make some of the risky assets redundant in the sense that one of them can be replicated on some predictable set by trading in the other ones. As a consequence, there may exist different strategies with the same gains process, and so a trading strategy is not uniquely determined (even up to indistinguishability) by its gains process. Indeed, by the construction of the stochastic integral, two strategies $\psi$ and $\varphi$ in $\Theta_{S}$ have the same gains process up to indistinguishability if and only if $c^{M}(\psi-\varphi)=0$ and $a^{\top}(\psi-\varphi)=0 P_{B}$-a.e.; see Lemma 5.1 in [7]. Therefore the convergence of the gains processes $G\left(\vartheta^{n}\right)$ need not imply the pointwise convergence of the strategies $\vartheta^{n}$, and so the pointwise closedness of $C(\omega, t)$ is not sufficient to deduce that $\vartheta$ can be chosen to be $C$-valued. However, the convergence of the gains processes is sufficient to prove that we do get a convergent sequence $\left(\psi^{n}\right)$ of modified strategies which have the same gains processes as the strategies
$\vartheta^{n}$. This sequence is given by the projection of $\left(\vartheta^{n}\right)$ on the predictable range of $S$.
Proposition 3.10. For each $\mathbb{R}^{d}$-valued semimartingale $Y$, there exists an $\mathbb{R}^{d \times d}$-valued predictable process $\Pi^{Y}$, called the projection on the predictable range of $Y$, which takes values in the orthogonal projections in $\mathbb{R}^{d}$ and has the following property: If $\vartheta \in \mathcal{L}(Y)$ and $\varphi$ is predictable, then $\varphi$ is in $\mathcal{L}(Y)$ with $\int \varphi d Y=\int \vartheta d Y$ (up to indistinguishability) if and only if $\Pi^{Y} \vartheta=\Pi^{Y} \varphi P_{B}$-a.e. We choose and fix one version of $\Pi^{Y}$.

Proof. See Lemma 5.3 in [7].
Remark 3.11. Suppose that $S$ satisfies (SC). Then the construction of the stochastic integral gives that $\int \psi d S=0$ if and only if $\int \psi d M=0$ and therefore that $\Pi^{S}$ and $\Pi^{M}$ coincide ( $P_{B^{-}}$-a.e.). Since $\int \psi d M=0$ if and only if $c^{M} \psi=0 P_{B^{-}}$-a.e., we see that $\psi=\vartheta-\Pi^{M} \vartheta$ is $P_{B}$-a.e. valued in $\operatorname{Ker}\left(c^{M}\right)$, the kernel of the matrix $c^{M}$. Moreover, since $\Pi^{M}$ is an orthogonal projection, so is $\mathbb{1}_{d \times d}-\Pi^{M}$, and therefore $\Pi^{M}=\Pi^{S}$ can be chosen as the pointwise orthogonal projection on range $\left(c^{M}(\omega, t)\right)$, the range of the matrix $c^{M}(\omega, t)$, which is equal to $\operatorname{Ker}\left(c^{M}(\omega, t)\right)^{\perp}$.

Using the projection on the predictable range, we can now prove the closedness in the constrained case.

Theorem 3.12. Assume that $\mathcal{E}=\mathcal{E}(N)$ is regular and satisfies $R_{2}(P)$, and that $S \in \mathcal{H}_{\mathrm{loc}}^{2}(P)$ is an $\mathcal{E}$-local martingale. Let $C: \bar{\Omega} \rightarrow 2^{\mathbb{R}^{d}}$ be a predictable correspondence with closed values and such that $\Theta_{S}(C)$ is non-empty. Then the spaces $G_{T}\left(\Theta_{S}(C)\right)$, $\mathcal{A}\left(\Theta_{S}(C)\right)$ and $L^{2}\left(\mathcal{B}_{0}\right)+G_{T}\left(\Theta_{S}(C)\right)$, for any $\sigma$-field $\mathcal{B}_{0} \subseteq \mathcal{F}_{0}$, are closed in $L^{2}(P)$ if and only if the projection of $C$ on the predictable range of $S$ is closed, i.e. $\Pi^{S}(\omega, t) C(\omega, t)$ is closed $P_{B}$-a.e.

Proof. " $\Leftarrow$ ": Let $\left(Y_{0}^{n}+G_{T}\left(\vartheta^{n}\right)\right)$ be a sequence in $L^{2}\left(\mathcal{B}_{0}\right)+G_{T}\left(\Theta_{S}(C)\right)$ converging to $H$ in $L^{2}(P)$. Then there exist some $Y_{0} \in L^{2}\left(\mathcal{B}_{0}\right)$ and some $\vartheta \in \Theta_{S}$ such that $Y_{0}+G_{T}(\vartheta)=H$ $P$-a.s. and $\left(Y_{0}^{n}+G\left(\vartheta^{n}\right)\right)$ converges to $Y_{0}+G(\vartheta)$ in $\mathcal{H}^{2}(P)$, by the proof of Proposition 3.8. The convergence in $\mathcal{H}^{2}(P)$ implies the convergence in the semimartingale topology by Theorem V. 14 and the lemma preceding Theorem IV. 12 in [24]. By Theorem 4.5 in [7], the space of stochastic integrals of $C$-valued integrands is closed in the semimartingale topology if the projection of $C$ on the predictable range of $S$ is closed. Thus there exists $\widetilde{\vartheta} \in \Theta_{S}(C)$ such that $G(\widetilde{\vartheta})=G(\vartheta)$, and therefore $L^{2}\left(\mathcal{B}_{0}\right)+G_{T}\left(\Theta_{S}(C)\right)$ is closed in $L^{2}(P)$. As in the proof of Proposition 3.8, choosing $\mathcal{B}_{0}=\{\emptyset, \Omega\}$ and $Y_{0}^{n}=0$ for all $n \in \mathbb{N}$ gives the closedness of $\mathcal{A}\left(\Theta_{S}\right)$ and $G_{T}\left(\Theta_{S}\right)$.
$" \Rightarrow "$ : First note that for any stopping time $\tau$, the projection $\Pi^{S^{\tau}}$ on the predictable range of $S^{\tau}$ is simply $\Pi^{S} \mathbb{1}_{[0, \tau]}$. Recall that $S \in \mathcal{H}_{\mathrm{loc}}^{2}(P)$. Arguing by contradiction, we choose a stopping time $\tau$ such that $S^{\tau} \in \mathcal{H}^{2}(P)$ and $\Pi^{S^{\tau}}$ is not closed. Applying

Lemma 4.4 in [7] with $S^{\tau}$ and using that $\int \varphi d S^{\tau}=\int \varphi \mathbb{1}_{[0, \tau]} d S$ for any $\varphi \in \mathcal{L}(S)$ implies that there exist $\vartheta \in \mathcal{L}(S)$ and a sequence $\left(\psi^{n}\right)$ of $C$-valued integrands such that $\left(\int \psi^{n} \mathbb{1}_{\llbracket 0, \tau \rrbracket} d S\right)$ converges to $\int \vartheta \mathbb{1}_{\llbracket 0, \tau \rrbracket} d S$ in the semimartingale topology, but there is no $C$-valued integrand $\psi$ such that $\int \psi \mathbb{1}_{[0, \tau \rrbracket} d S=\int \vartheta \mathbb{1}_{[0, \tau \rrbracket} d S$. An inspection of the proof of Lemma 4.4 in $[7]$ shows that we can choose $\vartheta$ and $\left(\psi^{n}\right)$ such that $\left(\Pi^{S} \vartheta\right) \mathbb{1}_{[0, \tau \rrbracket}$ and $\left(\Pi^{S} \psi^{n}\right) \mathbb{1}_{\llbracket 0, \tau \rrbracket}$ are uniformly bounded and $\left(\Pi^{S} \psi^{n}\right) \mathbb{1}_{\llbracket 0, \tau \rrbracket} \rightarrow\left(\Pi^{S} \vartheta\right) \mathbb{1}_{\llbracket 0, \tau \rrbracket}$ uniformly in $(\omega, t)$. Since $\int \psi^{n} \mathbb{1}_{\llbracket 0, \tau \rrbracket} d S=\int\left(\Pi^{S} \psi^{n}\right) \mathbb{1}_{\llbracket 0, \tau \rrbracket} d S$ and $\int \vartheta \mathbb{1}_{\llbracket 0, \tau \rrbracket} d S=\int\left(\Pi^{S} \vartheta\right) \mathbb{1}_{[0, \tau \rrbracket} d S$, we have by dominated convergence that $\int\left(\psi^{n} \mathbb{1}_{[0, \tau \rrbracket}+\varphi \mathbb{1}_{\rrbracket \tau, T \rrbracket}\right) d S \rightarrow \int \tilde{\vartheta} d S$ in $\mathcal{H}^{2}(P)$ for any $\varphi \in \Theta_{S}(C)$, with $\widetilde{\vartheta}=\vartheta \mathbb{1}_{\llbracket 0, \tau \rrbracket}+\varphi \mathbb{1}_{\rrbracket \tau, T \rrbracket}$, and hence also that $G_{T}\left(\psi^{n} \mathbb{1}_{\llbracket 0, \tau \rrbracket}+\varphi \mathbb{1}_{\rrbracket, T \rrbracket}\right) \rightarrow G_{T}(\widetilde{\vartheta})$ in $L^{2}(P)$ by Proposition 2.1. But because there exists by construction of $\widetilde{\vartheta}$ no $C$-valued integrand $\psi$ with $G(\psi)=G(\widetilde{\vartheta})$ and since $G(\widetilde{\vartheta})$ is uniquely determined in $\mathcal{H}^{2}(P)$ by its terminal value $G_{T}(\widetilde{\vartheta})$ by Proposition 3.7, there cannot be any $\psi \in \Theta_{S}(C)$ with $G_{T}(\psi)=G_{T}(\widetilde{\vartheta})$. This contradicts the closedness of $G_{T}\left(\Theta_{S}(C)\right)$ in $L^{2}(P)$ and therefore completes the proof.

For a better understanding of our assumptions, we now spell them out in a multidimensional Itô process model. This is one standard example of a financial market, and it illustrates that our assumptions are weaker than those in [19], [13] and [14].

Example 3.13. Let $W$ be an $\mathbb{R}^{n}$-valued Brownian motion on a filtered probability space $(\Omega, \mathcal{F}, \mathbb{F}, P)$ with a filtration satisfying the usual conditions. Note that for our results, $\mathbb{F}$ need not be the $P$-augmentation of the filtration generated by $W$; we do not use Itô's representation theorem. Let $\bar{S}=\left(\bar{S}^{i}\right)_{i=1, \ldots, d}$ be the undiscounted price processes of the $d$ risky assets and $\bar{S}^{0}$ the undiscounted price of the bank account. These processes are given as the solutions to the stochastic differential equations (SDEs)

$$
d \bar{S}_{t}^{i}=\bar{S}_{t}^{i}\left(\mu_{t}^{i} d t+\sum_{j=1}^{n} \sigma_{t}^{i j} d W_{t}^{j}\right), \quad \bar{S}_{0}^{i}=s_{0}^{i}
$$

for $i=1, \ldots, d$ with constants $s_{0}^{i}>0$ and

$$
d \bar{S}_{t}^{0}=\bar{S}_{t}^{0} r_{t} d t, \quad \bar{S}_{0}^{0}=1
$$

with predictable $\mathbb{R}^{d}$-, $\mathbb{R}$ - and $\mathbb{R}^{d \times n}$-valued processes $\mu, r$ and $\sigma$ that are $P$-a.s. on $[0, T]$ Lebesgue-integrable and Lebesgue-square-integrable, respectively. In our abstract setup, we consider the discounted prices $S^{i}=\bar{S}^{i} / \bar{S}^{0}$. The SDEs for the $S^{i}$ then take the form

$$
d S_{t}^{i}=S_{t}^{i}\left(\left(\mu_{t}^{i}-r_{t}\right) d t+\sum_{j=1}^{n} \sigma_{t}^{i j} d W_{t}^{j}\right), \quad S_{0}^{i}=s_{0}^{i}
$$

and we explicitly have

$$
\begin{aligned}
d\langle M\rangle_{t} & =\operatorname{diag}\left(S_{t}\right) \sigma_{t} \sigma_{t}^{\top} \operatorname{diag}\left(S_{t}\right) d t=: c_{t}^{M} d t \\
d A_{t} & =\operatorname{diag}\left(S_{t}\right)\left(\mu_{t}-r_{t} \mathbf{1}\right) d t=: a_{t} d t
\end{aligned}
$$

with $\mathbf{1}=(1 \ldots 1)^{\top} \in \mathbb{R}^{d}$. Up to integrability conditions on $\mu, r$ and $\sigma$, the process $S$ satisfies (SC) if and only if $(\mu-r \mathbf{1}) \in \operatorname{range}\left(\sigma \sigma^{\top}\right) d P \otimes d t$-a.e., since $S_{t}^{i}>0$ for $i=1, \ldots, d$. For a sufficient condition for this, we assume that $\sigma \sigma^{\top}$ is $d P \otimes d t$-a.e. invertible, which means that $n \geq d$ and that $\sigma$ has $d P \otimes d t$-a.e. full rank $d$. This condition also implies that $\Pi^{S}=\mathbb{1}_{d \times d}$ and therefore that the projection of any closed-valued predictable correspondence $C$ on the predictable range of $S$ is closed. A natural candidate to obtain a local martingale $N$ such that $S$ is an $\mathcal{E}(N)$-martingale is $N=-\int \lambda d M=-\int \varphi d W$, where $\varphi=\sigma^{\top} \lambda=\sigma^{\top}\left(\sigma \sigma^{\top}\right)^{-1}(\mu-r \mathbf{1})$ is the instantaneous market price of risk. Here we make the frequently used assumption that the mean-variance tradeoff (MVT) process

$$
K_{t}:=\int_{0}^{t} \lambda_{s}^{\top} d\langle M\rangle_{s} \lambda_{s}=\left\langle\int \lambda d M\right\rangle_{t}=\left\langle\int \varphi d W\right\rangle_{t}=\int_{0}^{t}\left|\varphi_{s}\right|^{2} d s
$$

which coincides in this setup with the integrated squared market price of risk, is uniformly bounded in $t$ and $\omega$. This is sufficient to guarantee that $\mathcal{E}\left(-\int \lambda d M\right)$ is a true martingale and satisfies $R_{2}(P)$ by Proposition 3.7 in [4]. As $M$ is continuous, $\mathcal{E}\left(-\int \lambda d M\right)$ is strictly positive and $d \widehat{P}=\mathcal{E}\left(-\int \lambda d M\right)_{T} d P$ defines an equivalent local martingale measure (ELMM) for the process $S$, the so-called minimal martingale measure; see [27].

Thus we can conclude that if the MVT process $K$ is uniformly bounded in $t$ and $\omega$ and $\sigma \sigma^{\top}$ is $d P \otimes d t$-a.e. invertible, the assumptions of Theorem 3.12 are satisfied and $G_{T}\left(\Theta_{S}(C)\right)$ and $\mathcal{A}\left(\Theta_{S}(C)\right)$ are closed in $L^{2}(P)$ for all closed-valued, predictable correspondences $C$. If we suppose in addition that $\bar{S}_{T}^{0}$ and $1 / \bar{S}_{T}^{0}$ are in $L^{\infty}(P)$, which holds for instance if $r$ is uniformly bounded in $t$ and $\omega$, then also the corresponding sets $\bar{S}_{T}^{0} G_{T}\left(\Theta_{S}(C)\right), \bar{S}_{T}^{0}\left(x+G_{T}\left(\Theta_{S}(C)\right)\right)$ and $\bar{S}_{T}^{0} \mathcal{A}\left(\Theta_{S}(C)\right)$ of undiscounted payoffs attainable with constrained trading strategies considered in [19], [13] and [14] are closed in $L^{2}(P)$.

Our assumptions are clearly far less restrictive than completeness of the (unconstrained) financial market. The latter is imposed in [19] and [13] by the conditions that $\mu, r$ and $\sigma$ are uniformly bounded in $t$ and $\omega$, that $\sigma^{-1}$ exists and is uniformly bounded in $t$ and $\omega$ as well, and that $\mathbb{F}$ is the $P$-augmentation of the filtration generated by $W$. The last two assumptions allow to use Itô's representation theorem and then rewrite integrals of $W$ as integrals of $S$.

In [19] and [13], the constraints are not formulated in terms of number of shares $\vartheta^{i}$, but in terms of the cash amounts $\pi^{i}:=\vartheta^{i} \bar{S}^{i}$ invested in the different assets. To see that this can also be handled in our formulation, let $C^{\pi}$ be a closed-valued predictable correspondence which describes constraints on the cash amounts. Extending [19] and [13], this need not be deterministic. Since $\bar{S}^{i}>0$, we can define the correspondence $C^{\vartheta}$ by
$C^{\vartheta}(\omega, t):=\operatorname{diag}\left(\bar{S}^{i}(\omega, t)\right)^{-1} C^{\pi}(\omega, t)$, which is by Proposition 2.4 again a closed-valued predictable correspondence and describes by definition the same constraints as $C^{\pi}$, but in number of shares. Alternatively, we can consider the dynamics of the gains process parametrised in cash amounts, i.e.

$$
\begin{aligned}
d G_{t}(\vartheta) & =\vartheta_{t}^{\top} \operatorname{diag}\left(S_{t}\right)\left(\mu_{t}-r_{t} \mathbf{1}\right) d t+\vartheta_{t}^{\top} \operatorname{diag}\left(S_{t}\right) \sigma_{t} d W_{t} \\
& =\pi_{t}^{\top} \frac{1}{\bar{S}_{t}^{0}}\left(\mu_{t}-r_{t} \mathbf{1}\right) d t+\pi_{t}^{\top} \frac{1}{\bar{S}_{t}^{0}} \sigma_{t} d W_{t}=\pi_{t}^{\top} d X_{t}, \quad G_{0}(\vartheta)=G_{0}(\pi)=0
\end{aligned}
$$

with the discounted returns process

$$
d X_{t}=\frac{1}{\bar{S}_{t}^{0}}\left(\mu_{t}-r_{t} \mathbf{1}\right) d t+\frac{1}{\bar{S}_{t}^{0}} \sigma_{t} d W_{t}, \quad X_{0}=\mathbf{1}
$$

as integrator. Then we can apply our results to the stochastic integrals $\int \pi d X$ with

$$
\pi \in \Theta_{X}\left(C^{\pi}\right):=\left\{\pi \in \mathcal{L}(X) \mid \int \pi d X \in \mathcal{H}^{2}(P) \text { and } \pi(\omega, t) \in C^{\pi}(\omega, t) \text { for all }(\omega, t) \in \bar{\Omega}\right\}
$$

rather than $\int \vartheta d S$ with $\vartheta \in \Theta_{S}\left(C^{\vartheta}\right)$ to obtain that $G_{T}\left(\Theta_{X}\left(C^{\pi}\right)\right)=G_{T}\left(\Theta_{S}\left(C^{\vartheta}\right)\right)$ is closed in $L^{2}(P)$. In this parametrisation, each (undiscounted) payoff in $\bar{S}_{T}^{0}\left(x+G_{T}\left(\Theta_{X}\left(C^{\pi}\right)\right)\right)$ is the final value $\bar{V}_{T}(x, \pi)$ of the wealth process of a self-financing trading strategy, where $\bar{V}(x, \pi)$ is given by the solution of the SDE

$$
d \bar{V}_{t}(x, \pi)=\left(\bar{V}_{t}(x, \pi) r_{t}+\pi_{t}^{\top}\left(\mu_{t}-r_{t} \mathbf{1}\right)\right) d t+\pi_{t}^{\top} \sigma_{t} d W_{t}, \quad \bar{V}_{0}(x, \pi)=x
$$

For no short-selling constraints, i.e. $C^{\pi}=[0,+\infty)^{d}$, Jin and Zhou in [14] do not (and do not need to) assume invertibility of $\sigma \sigma^{\top}$ to obtain a solution to the constrained Markowitz problem. The reason behind this is that as $[0,+\infty)^{d}$ is a polyhedral set, all its projections are closed. Of course, our results cover this case as well.

To obtain (the existence of) a solution to the mean-variance hedging problem under constraints, we assume in addition to the conditions of Theorem 3.12 that $C: \bar{\Omega} \rightarrow 2^{\mathbb{R}^{d}}$ also takes convex values. This gives the following relations to predictable convexity and stability which come up naturally in dynamic portfolio optimisation problems. The notion of predictable convexity was introduced in [11] to obtain an optional decomposition theorem under constraints, and stability of a set of strategies is usually assumed to establish a dynamic programming principle. The next result and its proof are inspired by Theorems 3 and 4 in [8].

Proposition 3.14. Assume that $\mathcal{E}=\mathcal{E}(N)$ is regular and satisfies $R_{2}(P)$, and that $S \in \mathcal{H}_{\mathrm{loc}}^{2}(P)$ is an $\mathcal{E}$-local martingale. Let $\mathfrak{C} \subseteq \Theta_{S}$ be non-empty and such that $G_{T}(\mathfrak{C})$ is closed in $L^{2}(P)$. Then the following are equivalent:

1) The set $\mathfrak{C}$ is predictably convex, i.e. for all $\vartheta$ and $\varphi$ in $\mathfrak{C}$ and all $[0,1]$-valued predictable processes $k$, the strategy $k \vartheta+(1-k) \varphi$ is in $\mathfrak{C}$.
2) The set $\mathfrak{C}$ is convex and stable, i.e. for all $\vartheta$ and $\varphi$ in $\mathfrak{C}$, all $t \in[0, T]$ and all $F \in \mathcal{F}_{t}$, the strategy $\vartheta \mathbb{1}_{F^{c}}+\left(\vartheta \mathbb{1}_{[0, t]}+\varphi \mathbb{1}_{\rrbracket t, T \rrbracket}\right) \mathbb{1}_{F}$ is in $\mathfrak{C}$.
3) There exists a predictable correspondence $C: \bar{\Omega} \rightarrow 2^{\mathbb{R}^{d}}$ with non-empty, closed and convex values such that the projection of $C$ on the predictable range of $S$ is closed, i.e. $\Pi^{S}(\omega, t) C(\omega, t)$ is closed $P_{B}$-a.e., and

$$
G(\mathfrak{C})=\{G(\varphi) \mid \varphi \in \mathfrak{C}\}=\left\{G(\vartheta) \mid \vartheta \in \Theta_{S}(C)\right\}=G\left(\Theta_{S}(C)\right)
$$

Proof. The implication "1) $\Longrightarrow 2$ )" is obvious. For the remaining ones, we observe that by Proposition 3.7, the closedness of $G_{T}(\mathfrak{C})$ in $L^{2}(P)$ is equivalent to that of $G(\mathfrak{C})$ in $\mathcal{H}^{2}(P)$. The equivalence " 3$) \Longleftrightarrow 1$ )" then follows from part 2) of Remark 4.12 in [7], and $" 2) \Longrightarrow 1$ )" from (the arguments in the proof of) Lemma 11 in [8].

## 4 Existence of a solution

Having established the closedness of $G_{T}\left(\Theta_{S}(C)\right)$ and $\mathcal{A}\left(\Theta_{S}(C)\right)$, we are able to prove the existence of a solution to the mean-variance hedging problem under trading constraints by using the best approximation theorem in Hilbert spaces; see Theorem 1.4.1 in [2]. Although this looks very easy, it is worth pointing out that our result is given for a very general framework. It covers for instance the existence of a solution in the Itô process setting of Labbé and Heunis [19], Hu and Zhou [13], and Jin and Zhou [14]. We also emphasise that our approach provides a unified treatment for the above papers, which use different and more situation-based arguments like convex duality for Itô processes, Itô's representation theorem, linear-quadratic optimal control and BSDE techniques.

Theorem 4.1. Assume $\mathcal{E}=\mathcal{E}(N)$ is regular and satisfies $R_{2}(P)$, and that $S \in \mathcal{H}_{\mathrm{loc}}^{2}(P)$ is an $\mathcal{E}$-local martingale. Let $C: \bar{\Omega} \rightarrow 2^{\mathbb{R}^{d}}$ be a predictable correspondence with closed convex values such that $\Theta_{S}(C)$ is non-empty. Then the following hold for every $H \in L^{2}(P)$ :

1) There exists a solution $\widehat{\vartheta}(x) \in \Theta_{S}(C)$ to the problem

$$
E\left[\left|x+G_{T}(\vartheta)-H\right|^{2}\right]=\min _{\vartheta \in \Theta_{S}(C)}!
$$

2) There exists a solution $(\widehat{x}, \widehat{\vartheta}(\widehat{x})) \in \mathbb{R} \times \Theta_{S}(C)$ to the problem

$$
E\left[\left|x+G_{T}(\vartheta)-H\right|^{2}\right]=\min _{(x, \vartheta) \in \mathbb{R} \times \Theta_{S}(C)}!
$$

Proof. By Theorem 3.12, $G_{T}\left(\Theta_{S}(C)\right)$ and $\mathcal{A}\left(\Theta_{S}(C)\right)$ are closed and convex subsets of $L^{2}(P)$. Therefore Theorem 1.4.1 in [2] implies the existence of a unique best approximation of $H-x$ by an element in $G_{T}\left(\Theta_{S}(C)\right)$. This can be identified uniquely with an element $G(\widehat{\vartheta}(x))$ in $G\left(\Theta_{S}(C)\right)$ which gives some $\widehat{\vartheta}(x) \in \Theta_{S}(C)$ and proves 1). In the same way, we get a unique element $\widehat{v}$ in $\mathcal{A}\left(\Theta_{S}(C)\right)$ which is the best approximation to $H$ in $L^{2}(P)$, and $\widehat{v}$ can again be identified with an element $(\widehat{x}, \widehat{\vartheta}(\widehat{x}))$ in $\mathbb{R} \times \Theta_{S}(C)$.
Remark 4.2.1) As explained in Example 3.13, the assumptions of Theorem 4.1 are satisfied in the Itô process framework of [13] and [14]. By the argument in the proof of Theorem 11 in [14], obtaining a solution to the constrained Markowitz problem, i.e.

$$
\begin{align*}
& \text { minimise } \operatorname{Var}\left[\bar{V}_{T}(x, \pi)\right]=E\left[\left|\bar{V}_{T}(x, \pi)\right|^{2}\right]-z^{2}  \tag{4.1}\\
& \text { subject to } \pi \in \Theta_{X}\left(K^{\pi}\right) \text { and } E\left[\bar{V}_{T}(x, \pi)\right]=z
\end{align*}
$$

for $z \geq x E\left[\bar{S}_{T}^{0}\right]$ and a predictable correspondence $K^{\pi}$ with closed and convex cones as values, is equivalent to finding a solution to

$$
E\left[\left(\bar{V}_{T}(x, \pi)-\left(m_{1}-m_{2} \mathcal{E}\left(-\int \lambda d M-\int r d t\right)_{T}\right)\right)^{2}\right]=\min _{\pi \in \Theta_{X}\left(K^{\pi}\right)}!
$$

for a suitable pair $\left(m_{1}, m_{2}\right) \in \mathbb{R}^{2}$ of Lagrange multipliers. Therefore the existence of a solution to (4.1) follows from Theorem 4.1 above. The dynamic structure of this solution in a general semimartingale framework is established in [6], which generalises the results obtained for a complete Itô process model in Theorem 6.3 in [13].
2) The problem studied in [19] in an Itô process framework is

$$
E\left[\frac{1}{2}\left(\bar{a}\left|\bar{V}_{T}(x, \pi)\right|^{2}+\bar{c} V_{T}(x, \pi)\right)\right]+q=\min _{\pi \in \Theta_{X}\left(C^{\pi}\right)}!
$$

where $\bar{a}>0$ and $1 / \bar{a}$ are in $L^{\infty}(P), \bar{c} \in L^{2}(P), q \in \mathbb{R}$ and $C^{\pi} \equiv K \subseteq \mathbb{R}^{d}$ is a fixed closed and convex set; see Problem (5.2) in [19]. To obtain a solution to this problem, we observe that $\bar{a} \bar{S}_{T}^{0}\left(x+G_{T}\left(\Theta_{X}\left(C^{\pi}\right)\right)\right)$ is convex and closed in $L^{2}(P)$, since $\bar{a}$ and $1 / \bar{a}$ are in $L^{\infty}(P)$, and that we can write

$$
E\left[\frac{1}{2}\left(\bar{a}\left|\bar{V}_{T}(x, \pi)\right|^{2}+\bar{c} V_{T}(x, \pi)\right)\right]+q=\frac{1}{2} E\left[\left|\bar{a} \bar{V}_{T}(x, \pi)+\frac{\bar{c}}{2 \bar{a}}\right|^{2}\right]-E\left[\left|\frac{\bar{c}}{2 \bar{a}}\right|^{2}\right]+q
$$

Then the existence of a solution follows as in the proof of Theorem 4.1 by the best approximation theorem.

In order to handle also constraints on the trajectory of the wealth process, we use a simple martingale argument which already appears in [3], in a complete Itô process model. For that, we define the set of equivalent local martingale measures (ELMMs) for $S$ with $P$-square-integrable density by

$$
\mathbb{P}_{e}^{2}(S)=\left\{Q \sim P \mid S \text { is a local } Q \text {-martingale and } \frac{d Q}{d P} \in L^{2}(P)\right\} .
$$

Proposition 4.3. Suppose that $S \in \mathcal{H}_{\mathrm{loc}}^{2}(P)$ and that $\mathbb{P}_{e}^{2}(S) \neq \emptyset$. Let $J$ be a closed interval in $\mathbb{R}$. Then the following hold for any $\vartheta \in \Theta_{S}$ and any $x \in \mathbb{R}$ :

1) $G(\vartheta)$ takes values in $J$ P-a.s. if and only if its final value $G_{T}(\vartheta)$ does.
2) The wealth process $V(x, \vartheta)$ takes values in $J P$-a.s. if and only if its final value $V_{T}(x, \vartheta)$ does.
Proof. Since $V(x, \vartheta)=x+G(\vartheta)$, the proofs for 1) and 2) are completely analogous, and the "only if" part is obvious. For the "if" part, choose $Q \in \mathbb{P}_{e}^{2}(S)$ and write $J=\left[b_{1}, b_{2}\right]$ with $b_{1}, b_{2} \in \mathbb{R}$. Because $Q$ and $P$ are equivalent, we can write a.s. without specifying which measure is meant. Moreover, the density process $Z^{Q}$ is strictly positive and can be represented as a stochastic exponential $Z^{Q}=\mathcal{E}\left(L^{Q}\right)$ with $L^{Q}=\int \frac{1}{Z_{-}^{Q}} d Z^{Q}$. In the proof of part 1) of Proposition 3.8, the only point which uses the assumption that $R_{2}(P)$ is satisfied is to ensure that ${ }^{\tau} \mathcal{E}(N)$ is a $P$-square-integrable $P$-martingale for all stopping times $\tau$ by Proposition 3.6. However, as this is already known for $Z^{Q}=\mathcal{E}\left(L^{Q}\right)$, we can apply the same arguments here to obtain that $G(\vartheta)$ is a $Q$-martingale for all $\vartheta \in \Theta_{S}$. Hence $b_{1} \leq G_{T}(\vartheta) \leq b_{2}$ a.s. implies that $b_{1} \leq G_{t}(\vartheta) \leq b_{2}$ for all $t \in[0, T]$ a.s. For an infinite interval, the argument is analogous.

Combining the previous result with the $L^{2}$-closedness of the space of terminal gains allows us to solve the mean-variance hedging problem also under constraints on the trajectory of the wealth process, again via the best approximation theorem.

Proposition 4.4. Suppose that $S \in \mathcal{H}_{\mathrm{loc}}^{2}(P)$ and that there exists $Q \in \mathbb{P}_{e}^{2}(S)$ such that its density process $Z^{Q}$ satisfies $R_{2}(P)$. Then the following hold for every $H \in L^{2}(P)$ and every closed interval $J$ in $\mathbb{R}$ :

1) With $\mathcal{G}_{c}\left(\Theta_{S}\right)=\left\{G_{T}(\vartheta) \in G_{T}\left(\Theta_{S}\right) \mid G_{t}(\vartheta) \in J\right.$ for all $t \in[0, T] P$-a.s. $\}$, there exists a unique solution $\widehat{g}(x) \in \mathcal{G}_{c}\left(\Theta_{S}\right)$ to the problem

$$
E\left[|x+g-H|^{2}\right]=\min _{g \in \mathcal{G}_{c}\left(\Theta_{S}\right)}!
$$

2) With $\mathcal{A}_{c}\left(\Theta_{S}\right)=\left\{V_{T}(x, \vartheta) \in \mathcal{A}\left(\Theta_{S}\right) \mid V_{t}(x, \vartheta) \in J\right.$ for all $t \in[0, T] P$-a.s. $\}$, there exists a unique solution $\widehat{v} \in \mathcal{A}_{c}\left(\Theta_{S}\right)$ to the problem

$$
E\left[|v-H|^{2}\right]=\min _{v \in \mathcal{A}_{c}\left(\Theta_{S}\right)}!
$$

Proof. Thanks to Proposition 3.8, $G_{T}\left(\Theta_{S}\right)$ and $\mathcal{A}\left(\Theta_{S}\right)$ are closed in $L^{2}(P)$. By Proposition 4.3, we have

$$
\begin{aligned}
\left\{G_{T}(\vartheta) \in G_{T}\left(\Theta_{S}\right) \mid G_{t}(\vartheta)\right. & \in J \text { for all } t \in[0, T] P \text {-a.s. }\} \\
\left\{V_{T}(x, \vartheta) \in \mathcal{A}\left(\Theta_{S}\right) \mid V_{t}(x, \vartheta) \in J \text { for all } t \in[0, T] P \text {-a.s. }\right\} & =\left\{a \in \mathcal{A}\left(\Theta_{S}\right) \mid a \in J P \text {-a.s. }\right\}
\end{aligned}
$$

Moreover, we have $\left\{g \in G_{T}\left(\Theta_{S}\right) \mid g \in J P\right.$-a.s. $\}=G_{T}\left(\Theta_{S}\right) \cap\left\{f \in L^{2}(P) \mid f \in J P\right.$-a.s. $\}$ and $\left\{v \in \mathcal{A}\left(\Theta_{S}\right) \mid v \in J P\right.$-a.s. $\}=\mathcal{A}\left(\Theta_{S}\right) \cap\left\{f \in L^{2}(P) \mid f \in J P\right.$-a.s. $\}$. Since $J \subseteq \mathbb{R}$ is closed, the set $\left\{f \in L^{2}(P) \mid f \in J P\right.$-a.s. $\}$ is closed in $L^{2}(P)$ and therefore so are $\left\{g \in G_{T}\left(\Theta_{S}\right) \mid g \in J P\right.$-a.s. $\}$ and $\left\{a \in \mathcal{A}\left(\Theta_{S}\right) \mid a \in J P\right.$-a.s. $\}$. An application of the best approximation theorem completes the proof.

## 5 Convex duality

While the existence result in Theorem 4.1 is valid in a general framework, its easy proof has the drawback that it only gives the existence of a solution without any further properties. This is one motivation to study mean-variance hedging problems under trading constraints by means of convex duality. Typically, this provides additional insights into the structure of the solution, e.g. that the value functions of the primal and dual problems are continuously differentiable, strictly concave or convex, respectively, and conjugate to each other. Moreover, the solution of the primal problem is linked via the inverse of the "marginal utility" to the solution of the dual problem.

The general outline of these arguments follows the classical approach of Kramkov and Schachermayer [18] to maximising the expected utility from terminal wealth. The main idea we adopt from there is to treat the problem first as a static optimisation problem. This can be handled easily since we can apply duality theory in a Hilbert space. The obtained duality and existence results are then transferred back to the level of stochastic processes. Like for the existence of a solution, the required condition to establish this dual formulation is the closedness of the set $G_{T}\left(\Theta_{S}(C)\right)$. Of course, there is a lot of related work in the literature; we discuss this in more detail in Section 5.3 below.

To emphasise the analogy with utility maximisation, we rewrite the mean-variance hedging problem as a maximisation problem. This is then our primal problem and consists of finding the optimal trading strategy over time.

## Primal problem (stochastic processes):

$$
\begin{equation*}
E\left[-\frac{1}{2}\left|x+G_{T}(\vartheta)-H\right|^{2}\right]=\max _{\vartheta \in \Theta_{S}(C)}! \tag{5.1}
\end{equation*}
$$

The objective function in (5.1) is $U(x, \omega)=-\frac{1}{2}|x-H(\omega)|^{2}$, which depends on the state $\omega$ and is strictly convex and continuously differentiable in $x$. Its derivative and the inverse of that are $U^{\prime}(x, \omega)=-x+H(\omega)$ and $I(y, \omega)=\left(U^{\prime}\right)^{-1}(y, \omega)=-y+H(\omega)$. Since $U$ fails to be monotonic in $x$, it is not a utility function in the proper sense. But as it satisfies the other properties of a utility function and represents our preferences, we call it a "quadratic utility function".

Now observe that (5.1) only involves the terminal wealth $x+G_{T}(\vartheta)$. Hence we do not change the optimal value if we regard (5.1) as an optimisation problem over the set of
square-integrable random variables defined by

$$
\mathcal{C}(x)=\left\{f \in L^{2}(P) \mid f=x+G_{T}(\vartheta) \text { for some } \vartheta \in \Theta_{S}(C)\right\}=x+G_{T}\left(\Theta_{S}(C)\right) .
$$

This leads to the corresponding static optimisation problem, which runs only over a set of random variables.

## Primal problem (random variables):

$$
\begin{equation*}
E[U(f)]=E\left[-\frac{1}{2}|f-H|^{2}\right]=\max _{f \in \mathcal{C}(x)}! \tag{5.2}
\end{equation*}
$$

By construction, both problems have the same value function

$$
u(x)=\sup _{\vartheta \in \Theta_{S}(C)} E\left[U\left(x+G_{T}(\vartheta)\right)\right]=\sup _{f \in \mathcal{C}(x)} E[U(f)]
$$

### 5.1 Duality for static variables

If $C: \bar{\Omega} \rightarrow 2^{\mathbb{R}^{d}}$ is a predictable correspondence with closed convex values and the assumptions of Theorem 3.12 are satisfied, we obtain from there that $G_{T}\left(\Theta_{S}(C)\right)$ is a closed convex subset of $L^{2}(P)$. Thus the set of primal variables has the general structure

$$
\mathcal{C}(x)=x+\mathcal{G}_{c},
$$

where

$$
\begin{equation*}
\mathcal{G}_{c} \text { is a non-empty, closed and convex subset of } L^{2}(P) \text {. } \tag{5.3}
\end{equation*}
$$

Moreover, the assumptions of Theorem 3.12 also imply that with $\mathcal{G}=\operatorname{span}\left\{\mathcal{G}_{c}\right\}$, the set

$$
\mathbb{P}_{s}^{2}(\mathcal{G})=\left\{Q \ll P \mid Q \text { is a signed measure with } Q[\Omega]=1, \frac{d Q}{d P} \in L^{2}(P) \text { and } \frac{d Q}{d P} \in \mathcal{G}^{\perp}\right\}
$$

of signed $\mathcal{G}$-martingale measures is non-empty, where $\mathcal{G}^{\perp}$ denotes the orthogonal complement of $\mathcal{G}$ in $L^{2}(P)$. Hence we also suppose in our abstract static setting that

$$
\begin{equation*}
\mathbb{P}_{s}^{2}(\mathcal{G}) \neq \emptyset \tag{5.4}
\end{equation*}
$$

We emphasise that these simple structural properties will be enough to establish the desired duality results in the static setting. To obtain a dual characterisation of the primal variables, we use the following characterisation of closed convex sets $\mathfrak{K}$ in a Hilbert space $\mathfrak{H}$; see Theorem 2.5.1 in [2]. For any $k \in \mathfrak{H}$,

$$
k \in \mathfrak{K} \quad \Longleftrightarrow \quad(h, k)_{\mathfrak{H}} \leq \sup _{k^{\prime} \in \mathfrak{K}}\left(h, k^{\prime}\right)_{\mathfrak{H}}=: \delta(h \mid \mathfrak{K}), \quad \forall h \in \mathfrak{H},
$$

where $(\cdot, \cdot)_{\mathfrak{H}}$ denotes the scalar product in $\mathfrak{H}$ and $\delta(h \mid \mathfrak{K}):=\sup _{k^{\prime} \in \mathfrak{K}}\left(h, k^{\prime}\right)_{\mathfrak{H}}$ is the support function of $\mathfrak{K}$. It is easy to see that the support function of a general non-empty set is positively homogeneous, convex, lower semicontinuous and bounded from below by $-\min _{k \in \mathfrak{K}}\|k\|_{\mathfrak{H}}\|h\|_{\mathfrak{H}}$, which is finite if $\mathfrak{K}$ is non-empty; see Proposition 2.5.1 in [2]. Applying this characterisation to $\mathcal{G}_{c}$ and $L^{2}(P)$, we obtain for any $g \in L^{2}(P)$ that

$$
\begin{equation*}
g \in \mathcal{G}_{c} \quad \Longleftrightarrow \quad E[h g] \leq \sup _{g^{\prime} \in \mathcal{G}_{c}} E\left[h g^{\prime}\right]=: \delta\left(h \mid \mathcal{G}_{c}\right), \quad \forall h \in L^{2}(P) \tag{5.5}
\end{equation*}
$$

where $\delta\left(\cdot \mid \mathcal{G}_{c}\right)$ is the support function of the set $\mathcal{G}_{c}$.
To deduce dual variables from the characterisation (5.5), we observe from [18], [21] and [23] that for the general outline of the arguments for the dual approach to hold, the dual variables should have the following properties. First, they should be defined in such a way that the dual problem, which is an optimisation problem over the set of dual variables, attains its solution. Since the primal problem is a maximisation for a concave function, the dual problem is a minimisation for a convex function. Thus it should be enough for the existence of a solution that the set of dual variables is convex and closed. Second, one should be able to establish a duality relation between the sets of primal and dual variables that allows one to show that a natural candidate derived from the dual solution lies in the set of primal variables. This candidate is given by the inverse $I$ of the quadratic "marginal utility" applied to the dual solution, as follows typically from the first order condition for optimality in the dual problem. Third, to obtain that the value functions of the primal and dual problems are conjugate, the product of the parameters $x$ and $y$ of the primal and dual problem should appear in the upper bound for the expectation of a primal and a dual variable for the corresponding parameters.

Let us start with the last point. For a primal variable $f \in \mathcal{C}(x)$ and an element $h$ of $L^{2}(P)$, the general structure of the primal variables gives

$$
E[f h]=E[(x+g) h] \leq x E[h]+\delta\left(h \mid \mathcal{G}_{c}\right) .
$$

This motivates us to define the static dual variables by

$$
\mathcal{D}(y)=\left\{h \in L^{2}(P) \mid E[h]=y, \delta\left(h \mid \mathcal{G}_{c}\right)<\infty\right\} \quad \text { for } y \in \mathbb{R}
$$

because this gives the third of the above properties, i.e.

$$
\begin{equation*}
f \in \mathcal{C}(x), h \in \mathcal{D}(y) \quad \Longrightarrow \quad E[f h] \leq x y+\delta\left(h \mid \mathcal{G}_{c}\right) \tag{5.6}
\end{equation*}
$$

By continuity and linearity of the expectation and lower semicontinuity and convexity of the support function, the set $\mathcal{D}(y)$ is closed and convex in $L^{2}(P)$ and thus also likely to satisfy the first property listed above. Note that $\mathcal{D}(y)$ contains $y \frac{d Q}{d P}$ for any $Q \in \mathbb{P}_{s}^{2}(\mathcal{G})$ so that it is non-empty due to (5.4). The second property from above will follow via the dual characterisation (5.5) of convex closed sets in $L^{2}(P)$; see the proof of Theorem 5.7 later.

Remark 5.1. 1) For a linear subspace $\mathcal{G}_{c}=\mathcal{G}$, the characterisation (5.5) simplifies to orthogonality, and the dual domain becomes $\mathcal{D}(y)=\left\{h \in L^{2}(P) \mid E[h]=y, h \in \mathcal{G}_{c}^{\perp}\right\}$. Moreover, we have $\mathcal{D}(y)=y \mathbb{P}_{s}^{2}(\mathcal{G})$ for any $y \neq 0$. This is exploited in [12] for the dual formulation in the unconstrained case.
2) If $\mathcal{G}_{c}$ is a cone, the support function $\delta\left(\cdot \mid \mathcal{G}_{c}\right)$ only takes the values 0 and $\infty$ and (5.5) therefore reduces to the bipolar relation

$$
g \in \mathcal{G}_{c} \quad \Longleftrightarrow \quad E[h g] \leq 0, \quad \forall h \in \mathcal{G}_{c}^{\circ},
$$

where $\mathcal{G}_{c}^{\circ}=\left\{h \in L^{2}(P) \mid E[h g] \leq 0, \forall g \in \mathcal{G}_{c}\right\}$ is the polar of $\mathcal{G}_{c}$. Since $\mathcal{G}_{c}^{\circ}$ is again a cone, we have $\mathcal{D}(y)=y \mathcal{D}(1)$ for $y>0$ and $\mathcal{D}(y)=|y| \mathcal{D}(-1)$ for $y<0$. The sets $\mathcal{D}(1)$ and $\mathcal{D}(-1)$ can then be interpreted as the sets of all Radon-Nikodým derivatives of signed $\mathcal{G}_{c}$-super- and $\mathcal{G}_{c}$-submartingale measures, respectively. The above simplification explains why the majority of papers concentrate on constraints given by closed convex cones.

Returning to the general case, we work as usual with the Legendre transform $V$ in $x$ of $-U(-\cdot, \omega)$ to derive the formulation of the dual problem. The function $V$ is given by

$$
V(y, \omega)=\sup _{x \in \mathbb{R}}\{U(x, \omega)-x y\}=U(I(y, \omega))-I(y, \omega) y=\frac{1}{2} y^{2}-y H(\omega) ;
$$

it depends on the state $\omega$ and is continuously differentiable and strictly convex in $y$. The motivation for using the Legendre transform comes from looking for the sharpest inequality such that

$$
U(x, \omega) \leq V(y, \omega)+x y, \quad \forall x, y \in \mathbb{R}, \forall \omega \in \Omega
$$

Plugging in $f \in \mathcal{C}(x)$ and $h \in \mathcal{D}(y)$ for $x$ and $y$ in the above inequality, taking expectations and optimising on both sides gives via (5.6)

$$
\begin{align*}
u(x) & =\sup _{f \in \mathcal{C}(x)} E[U(f)] \leq \inf _{y \in \mathbb{R}}\left\{\inf _{h \in \mathcal{D}(y)} E[V(h)+g h]\right\} \\
& \leq \inf _{y \in \mathbb{R}}\left\{\inf _{h \in \mathcal{D}(y)}\left\{E[V(h)]+\delta\left(h \mid \mathcal{G}_{c}\right)\right\}+x y\right\}=\inf _{y \in \mathbb{R}}\{v(y)+x y\} \tag{5.7}
\end{align*}
$$

where the value function of the dual problem on the level of random variables is

$$
v(y)=\inf _{h \in \mathcal{D}(y)}\left\{E[V(h)]+\delta\left(h \mid \mathcal{G}_{c}\right)\right\}
$$

Note that the objective function of the dual problem explicitly involves the constraints via the support function $\delta$.

## Dual problem (random variables):

$$
\begin{equation*}
\Psi(h):=E[V(h)]+\delta\left(h \mid \mathcal{G}_{c}\right)=\min _{h \in \mathcal{D}(y)}! \tag{5.8}
\end{equation*}
$$

From the inequalities in (5.7), we see that if we can find for a given $x$ a pair $(\widehat{f}(x), \widehat{h}(y))$ of primal and dual variables such that equality holds in (5.7), we have also found a solution to the primal problem (5.2), as $\widehat{f}(x)$ attains the supremum. Of course, $y$ will then also depend on $x$. So an abstract recipe for solving the primal problem looks as follows:

1) Find the solution $\widehat{h}(y)$ to the dual problem (5.8) for any $y \in \mathbb{R}$.
2) Find the minimiser $\widehat{y}(x)$ for the indirect dual problem $v(y)+x y=\min _{y \in \mathbb{R}}$ !, for any $x \in \mathbb{R}$.
3) Define $\widehat{h}:=\widehat{h}(\widehat{y}(x)), \widehat{f}(x):=I(\widehat{h})$ and show that $E[I(\widehat{h}) \widehat{h}]=x \widehat{y}(x)+\delta\left(\widehat{h} \mid \mathcal{G}_{c}\right)$.
4) If we can show that $\widehat{f}(x) \in \mathcal{C}(x)$, then $\widehat{f}(x)$ solves (5.2), since we have by combining (5.7) with steps 1)-3) that

$$
\begin{aligned}
u(x) & \leq \inf _{y \in \mathbb{R}}\{v(y)+x y\}=v(\widehat{y}(x))+x \widehat{y}(x)=E[V(\widehat{h})]+\delta\left(\widehat{h} \mid \mathcal{G}_{c}\right)+x \widehat{y}(x) \\
& =E[U(I(\widehat{h}))-I(\widehat{h}) \widehat{h}]+\delta\left(\widehat{h} \mid \mathcal{G}_{c}\right)+x \widehat{y}(x)=E[U(\widehat{f}(x))] \leq u(x) .
\end{aligned}
$$

To solve the primal problem (5.2), it now remains to implement the above recipe. We start by solving the dual problem, making use of the following result from convex analysis; see Proposition 1.2 in [10].

Proposition 5.2. Let $B$ be a reflexive Banach space, $K$ a non-empty closed convex subset of $B$ and $F$ a strictly convex, coercive and lower semicontinuous function from $B$ into $\mathbb{R} \cup\{+\infty\}$ that is proper on $K$. Then there exists a unique solution $\widehat{b} \in K$ to

$$
F(b)=\min _{b \in K}!
$$

Taking $B=L^{2}(P)$ and $K=\mathcal{D}(y)$, we only need to check that the dual objective function $\Psi$ satisfies the properties of $F$ to apply the proposition.

Lemma 5.3. For every $H \in L^{2}(P)$, the mapping

$$
h \mapsto \Psi(h)=E[V(h)]+\delta\left(h \mid \mathcal{G}_{c}\right)=E\left[\frac{1}{2} h^{2}-h H\right]+\delta\left(h \mid \mathcal{G}_{c}\right)
$$

from $L^{2}(P)$ into $\mathbb{R} \cup\{+\infty\}$ is strictly convex, lower semicontinuous, coercive and uniformly bounded from below by $-\frac{1}{2}\left(\|H\|_{L^{2}(P)}+\min _{g \in \mathcal{G}_{c}}\|g\|_{L^{2}(P)}\right)^{2}$.

Proof. We begin by proving that the mapping $h \mapsto E[V(h)]$ from $L^{2}(P)$ into $\mathbb{R}$ is strictly convex and continuous. The first property follows immediately from the strict convexity
of the function $V(\cdot, \omega)$ for all $\omega \in \Omega$. If $\left(h_{n}\right)$ converges to $h$ in $L^{2}(P)$, then $\left(h_{n}\right)$ is bounded in $L^{2}(P)$ and the Cauchy-Schwarz inequality gives

$$
\begin{aligned}
& \left|E\left[\frac{1}{2} h_{n}^{2}-h_{n} H\right]-E\left[\frac{1}{2} h^{2}-h H\right]\right|=\left|E\left[\left(h_{n}-h\right)\left(\frac{1}{2}\left(h_{n}+h\right)-H\right)\right]\right| \\
& \leq\left\|h_{n}-h\right\|_{L^{2}(P)}\left(\frac{1}{2}\left(\sup _{n \in \mathbb{N}}\left\|h_{n}\right\|_{L^{2}(P)}+\|h\|_{L^{2}(P)}\right)+\|H\|_{L^{2}(P)}\right) \xrightarrow{n \rightarrow \infty} 0,
\end{aligned}
$$

which proves the claimed continuity. Since $\delta\left(\cdot \mid \mathcal{G}_{c}\right)$ is convex and lower semicontinuous, the sum $\Psi(\cdot)=E[V(\cdot)]+\delta\left(\cdot \mid \mathcal{G}_{c}\right)$ is strictly convex and lower semicontinuous. Moreover, Cauchy-Schwarz implies that

$$
\begin{align*}
\Psi(h) & =E\left[\frac{1}{2} h^{2}-h H\right]+\delta\left(h \mid \mathcal{G}_{c}\right)  \tag{5.9}\\
& \geq \frac{1}{2}\|h\|_{L^{2}(P)}^{2}-\|h\|_{L^{2}(P)}\left(\|H\|_{L^{2}(P)}+\min _{g \in \mathcal{G}_{c}}\|g\|_{L^{2}(P)}\right)
\end{align*}
$$

which gives coercivity, since the right-hand side tends to $\infty$ as $\|h\|_{L^{2}(P)} \rightarrow \infty$ because $\min _{g \in \mathcal{G}_{c}}\|g\|_{L^{2}(P)}$ is finite. Minimising the right-hand side over $\|h\|_{L^{2}(P)}$ also gives the asserted lower bound, which completes the proof.

From the definition of $\mathcal{D}(y)$, we have that $y \frac{d Q}{d P}$ is in $\mathcal{D}(y)$ for every $y \in \mathbb{R}$ and $Q \in \mathbb{P}_{s}^{2}(\mathcal{G})$. Since $\delta\left(\left.y \frac{d Q}{d P} \right\rvert\, \mathcal{G}_{c}\right)=0$, assumption (5.4) implies that $\Psi$ is proper on $\mathcal{D}(y)$ for each $y \in \mathbb{R}$. Therefore all the conditions of Proposition 5.2 are satisfied in the setting of the dual problem, and the existence of a solution to the dual problem follows by combining Lemma 5.3 with Proposition 5.2. This gives

Proposition 5.4. Under the assumptions (5.3) and (5.4), there exists a unique solution $\widehat{h}(y) \in \mathcal{D}(y)$ to the dual problem (5.8) for every $H \in L^{2}(P)$ and each $y \in \mathbb{R}$, i.e.

$$
\Psi(\widehat{h}(y))=E[V(\widehat{h}(y))]+\delta\left(\widehat{h}(y) \mid \mathcal{G}_{c}\right)=\inf _{h \in \mathcal{D}(y)} E[V(h)]+\delta\left(h \mid \mathcal{G}_{c}\right)=v(y) .
$$

By Proposition 5.4, the function $v$ inherits all nice properties of $\Psi$, which enables us to solve the indirect dual problem by again using Proposition 5.2. More precisely:

Lemma 5.5. Under the assumptions (5.3) and (5.4), the function $v$ is strictly convex, continuous and coercive.

Proof. If $y_{1}, y_{2} \in \mathbb{R}$ and $\mu \in(0,1)$, then $\mu \widehat{h}\left(y_{1}\right)+(1-\mu) \widehat{h}\left(y_{2}\right) \in \mathcal{D}\left(\mu y_{1}+(1-\mu) y_{2}\right)$; so

$$
\begin{aligned}
\mu v\left(y_{1}\right)+(1-\mu) v\left(y_{2}\right) & =\mu \Psi\left(\widehat{h}\left(y_{1}\right)\right)+(1-\mu) \Psi\left(\widehat{h}\left(y_{2}\right)\right) \\
& >\Psi\left(\mu \widehat{h}\left(y_{1}\right)+(1-\mu) \widehat{h}\left(y_{2}\right)\right) \geq v\left(\mu y_{1}+(1-\mu) y_{2}\right)
\end{aligned}
$$

by Proposition 5.4 and the strict convexity of $\Psi$. Hence $v$ is strictly convex, and continuous like any convex function on $\mathbb{R}$ with finite values; see Corollary II.10.1.1 in [25]. By Jensen's
inequality, $\|\widehat{h}(y)\|_{L^{2}(P)} \geq E[\widehat{h}(y)]=y$ tends to $\infty$ as $y \rightarrow \infty$. Thus coercivity of $\Psi$ implies coercivity of $v$, again by Proposition 5.4. Note that in view of (5.9), $v(y)$ even grows quadratically as $|y| \rightarrow \infty$.

Since a continuous function is obviously proper, applying Proposition 5.2 to the strictly convex, continuous and coercive mapping $y \mapsto v(y)+x y$ on $\mathbb{R}$ immediately gives
Corollary 5.6. Assume (5.3) and (5.4). For every $x \in \mathbb{R}$, there exists a unique $\widehat{y}(x) \in \mathbb{R}$ that solves

$$
v(y)+x y=\min _{y \in \mathbb{R}}!
$$

Now we have everything in place to formulate and prove the abstract static version of the main result of this section.
Theorem 5.7. Suppose as in (5.3) that $\mathcal{G}_{c}$ is a non-empty, convex and closed subset of $L^{2}(P)$, and impose the assumption (5.4) that $\mathbb{P}_{s}^{2}(\mathcal{G}) \neq \emptyset$. Then:

1) For every $x \in \mathbb{R}$, there exists a unique solution $\widehat{f}(x) \in \mathcal{C}(x)$ to

$$
E\left[-\frac{1}{2}|f-H|^{2}\right]=\max _{f \in \mathcal{C}(x)}!
$$

It is given by

$$
\widehat{f}(x)=I(\widehat{h}(\widehat{y}(x)))=-\widehat{h}(\widehat{y}(x))+H
$$

where $\widehat{h}(\widehat{y}(x)) \in \mathcal{D}(\widehat{y}(x))$ and $\widehat{y}(x) \in \mathbb{R}$ are the unique solutions, respectively, to

$$
\Psi(h)=E\left[\frac{1}{2} h^{2}-h H\right]+\delta\left(h \mid \mathcal{G}_{c}\right)=\min _{h \in \mathcal{D}(\widehat{y}(x))}!
$$

and

$$
\begin{equation*}
v(y)+x y=\min _{y \in \mathbb{R}}! \tag{5.10}
\end{equation*}
$$

2) The value functions $u$ and $v$ are conjugate, i.e.

$$
\begin{aligned}
& u(x)=\inf _{y \in \mathbb{R}}\{v(y)+x y\}, \\
& v(y)=\sup _{x \in \mathbb{R}}\{u(x)-x y\},
\end{aligned}
$$

and continuously differentiable. $u$ is strictly concave and $v$ is strictly convex.
3) Furthermore, we have the equivalent relations

$$
\begin{align*}
E[\widehat{f}(x) \widehat{h}(\widehat{y}(x))] & =x \widehat{y}(x)+\delta\left(\widehat{h}(\widehat{y}(x)) \mid \mathcal{G}_{c}\right), \\
E\left[\widehat{f}(x) U^{\prime}(\widehat{f}(x))\right] & =x u^{\prime}(x)+\delta\left(U^{\prime}(\widehat{f}(x)) \mid \mathcal{G}_{c}\right),  \tag{5.11}\\
E\left[\widehat{h}(\widehat{y}(x)) V^{\prime}(\widehat{h}(\widehat{y}(x)))\right] & =\widehat{y}(x) v^{\prime}(\widehat{y}(x))-\delta\left(\widehat{h}(\widehat{y}(x)) \mid \mathcal{G}_{c}\right) .
\end{align*}
$$

Proof. 1) Since $\widehat{y}(x)$ and $\widehat{h}:=\widehat{h}(\widehat{y}(x))$ solve the problems (5.10) and (5.8), the definition of $\mathcal{D}(y)$ implies that $\widehat{h}(\widehat{y}(x))$ is also the solution to

$$
\begin{equation*}
\Psi(h)+x E[h]=\min _{h \in L^{2}(P)}!=\min _{h \in \mathcal{D}(\widehat{y}(x))}! \tag{5.12}
\end{equation*}
$$

For $\varepsilon \in(0,1)$ and $h \in L^{2}(P)$, set $h_{\varepsilon}=\widehat{h}+\varepsilon h$. Then optimality of $\widehat{h}$ for (5.12) gives

$$
\begin{align*}
0 & \leq \liminf _{\varepsilon \searrow 0} \frac{\Psi\left(h_{\varepsilon}\right)+x E\left[h_{\varepsilon}\right]-(\Psi(\widehat{h})+x E[\widehat{h}])}{\varepsilon} \\
& =\liminf _{\varepsilon \searrow 0}\left\{E[(\widehat{h}-H+x) h]+\frac{1}{2} \varepsilon E\left[h^{2}\right]+\frac{\delta\left(\widehat{h}+\varepsilon h \mid \mathcal{G}_{c}\right)-\delta\left(\widehat{h} \mid \mathcal{G}_{c}\right)}{\varepsilon}\right\}, \tag{5.13}
\end{align*}
$$

where the last expression is well defined as $\delta\left(\widehat{h} \mid \mathcal{G}_{c}\right)$ is finite. Hence we obtain by using $I(\widehat{h})=-\widehat{h}+H$ and the sublinearity of $\delta\left(\cdot \mid \mathcal{G}_{c}\right)$ that

$$
\begin{equation*}
E[(I(\widehat{h})-x) h] \leq \delta\left(h \mid \mathcal{G}_{c}\right), \quad \forall h \in L^{2}(P) \tag{5.14}
\end{equation*}
$$

and thus $I(\widehat{h})-x \in \mathcal{G}_{c}$, i.e. $I(\widehat{h}) \in \mathcal{C}(x)$, by the characterisation of closed convex sets in (5.5). Plugging $h=-\widehat{h}$ into (5.13) and using the positive homogeneity of $\delta\left(\cdot \mid \mathcal{G}_{c}\right)$ gives

$$
E[(I(\widehat{h})-x)(-\widehat{h})] \leq-\delta\left(\widehat{h} \mid \mathcal{G}_{c}\right) .
$$

Combining this with (5.14) for $h=\widehat{h}$ gives

$$
\begin{equation*}
\delta\left(\widehat{h} \mid \mathcal{G}_{c}\right)=E[(I(\widehat{h})-x) \widehat{h}]=E[I(\widehat{h}) \widehat{h}]-x \widehat{y}(x) \tag{5.15}
\end{equation*}
$$

Hence we obtain from (5.15) as in step 4) of the recipe before Proposition 5.2 that

$$
\begin{align*}
u(x) & \geq E[U(I(\widehat{h}))]=E[V(\widehat{h})+I(\widehat{h}) \widehat{h}] \\
& =E[V(\widehat{h})]+\delta\left(\widehat{h} \mid \mathcal{G}_{c}\right)+x \widehat{y}(x)=v(\widehat{y}(x))+x \widehat{y}(x) \geq u(x) \tag{5.16}
\end{align*}
$$

which shows that $\widehat{f}(x):=I(\widehat{h}(\widehat{y}(x)))$ indeed maximises $E[U(f)]$ over $\mathcal{C}(x)$.
2) Since we have equality in (5.16) and $\widehat{y}(x)$ attains $\inf _{y \in \mathbb{R}}\{v(y)+x y\}$, we also have that $u(x)=\inf _{y \in \mathbb{R}}\{v(y)+x y\}$ for all $x \in \mathbb{R}$ and then $v(y)=\sup _{x \in \mathbb{R}}\{u(x)-x y\}$ by the biconjugate property of the Legendre transform; see Theorem III.12.2 in [25]. To show the strict concavity of $u$, we fix $x_{1}, x_{2} \in \mathbb{R}$ and $\mu \in(0,1)$. Then $\mu \widehat{f}\left(x_{1}\right)+(1-\mu) \widehat{f}\left(x_{2}\right)$ is in $\mathcal{C}\left(\mu x_{1}+(1-\mu) x_{2}\right)$ and so part 1$)$ yields by the strict concavity of $U(\cdot, \omega)$ that

$$
\begin{aligned}
\mu u\left(x_{1}\right)+(1-\mu) u\left(x_{2}\right) & =E\left[\mu U\left(\widehat{f}\left(x_{1}\right)\right)+(1-\mu) U\left(\widehat{f}\left(x_{2}\right)\right)\right] \\
& <E\left[U\left(\mu \widehat{f}\left(x_{1}\right)+(1-\mu) \widehat{f}\left(x_{2}\right)\right)\right] \leq u\left(\mu x_{1}+(1-\mu) x_{2}\right) .
\end{aligned}
$$

Continuous differentiability of $u$ and $v$ follows since the Legendre transform of a strictly convex function is differentiable; see Theorems V.24.1 and V.26.3 in [25]. Since $v$ is continuously differentiable, we obtain for the minimiser $\widehat{y}(x)$ of $v(y)+x y$ over $y \in \mathbb{R}$ the relation $v^{\prime}(\widehat{y}(x))=-x$. Again by general results on the Legendre transform, we have

$$
V^{\prime}(\cdot, \omega)=-\left(U^{\prime}\right)^{-1}(\cdot, \omega)=-I(\cdot, \omega)
$$

and $v^{\prime}=-\left(u^{\prime}\right)^{-1}$; see Theorem V.23.5 in [25]. Combining this with $v^{\prime}(\widehat{y}(x))=-x$, $\widehat{f}(x)=I(\widehat{h})$ and (5.15) gives the relations (5.11). This completes the proof.

### 5.2 Duality for dynamic variables

Under the assumptions of Theorem 3.12, Theorem 5.7 already implies the existence of a unique solution to the primal problem (5.1) by choosing $\mathcal{G}_{c}=G_{T}\left(\Theta_{S}(C)\right)$, i.e. there exists an optimal trading strategy $\widehat{\vartheta}(x) \in \Theta_{S}(C)$ such that $\widehat{f}(x)=x+G_{T}(\widehat{\vartheta}(x))$. In particular, we recover part 2) of Theorem 4.1.

To establish an analogous duality result on the level of stochastic processes, we need a dynamic version for the dual variables. If we assume for simplicity that

$$
\mathcal{F}=\mathcal{F}_{T},
$$

we can identify every $h \in L^{2}(P)$ with a square-integrable RCLL martingale $Z=Z(h)$ given by $Z_{t}=E\left[h \mid \mathcal{F}_{t}\right]$ for $t \in[0, T]$. The Kunita-Watanabe decomposition then yields

$$
Z_{t}=E\left[h \mid \mathcal{F}_{0}\right]+\int_{0}^{t} \eta_{s} d M_{s}+R_{t}, \quad t \in[0, T],
$$

with $\eta \in L^{2}(M)$ and $R \in \mathcal{M}_{0}^{2}(P)$ strongly $P$-orthogonal to $M$. We choose this parametrisation because it makes it easy to calculate the dynamics of the product of a gains process and a dual variable. Moreover, it is similar to [5], where dual variables are supermartingale measures for the gains processes of constrained trading strategies. The parametrisation in [5] can be obtained by applying the Kunita-Watanabe decomposition to the stochastic logarithm of the density process, and in the Brownian filtration of [5], this decomposition can of course be replaced by Itô's representation theorem; see [5] and Example 3.2 in [21].

Lemma 5.8. Suppose that $S$ is in $\mathcal{H}_{\mathrm{loc}}^{2}(P)$ and satisfies the structure condition (SC). For every $\vartheta \in \Theta_{S}$ and every $Z \in \mathcal{M}^{2}(P)$, the process

$$
\begin{equation*}
\left(G_{t}(\vartheta) Z_{t}-\int_{0}^{t}\left(\eta_{s}+Z_{s-} \lambda_{s}\right)^{\top} c_{s}^{M} \vartheta_{s} d B_{s}\right)_{0 \leq t \leq T} \tag{5.17}
\end{equation*}
$$

is then a $P$-martingale with $P$-integrable supremum, i.e. a martingale in $\mathcal{H}^{1}(P)$.

Proof. Applying the product rule and using that $S$ satisfies (SC) gives

$$
d(G(\vartheta) Z)=Z_{-} \vartheta d M+Z_{-} \vartheta^{\top} d\langle M\rangle \lambda+G_{-}(\vartheta) d Z+d\left[Z, \int \vartheta d A\right]+d\left[Z, \int \vartheta d M\right] .
$$

Clearly, $\int Z_{-} \vartheta d M$ and $\int G_{-}(\vartheta) d Z$ are local $P$-martingales. Moreover, $\left\langle Z, \int \vartheta d M\right\rangle$ exists because $Z \in \mathcal{M}^{2}(P)$ and $\vartheta \in \mathcal{L}^{2}(M)$, and $\left[Z, \int \vartheta d A\right]$ is a local martingale by Yoeurp's lemma. Writing $\stackrel{\text { mart }}{=}$ for equality up to a local $P$-martingale and using that $R$ is strongly $P$-orthogonal to $M$, we thus obtain

$$
d(G(\vartheta) Z) \stackrel{\operatorname{mart}}{=} Z_{-} \vartheta^{\top} d\langle M\rangle \lambda+\vartheta^{\top} d\langle Z, M\rangle \stackrel{\operatorname{mart}}{=}\left(\eta+Z_{-} \lambda\right)^{\top} d\langle M\rangle \vartheta .
$$

This shows that the process in (5.17) is a local $P$-martingale. To check integrability, we first observe that by Doob's inequality and Proposition 2.1, $(Z G(\vartheta))_{T}^{*}$ is in $L^{1}(P)$ since $Z \in \mathcal{M}^{2}(P)$ and $G(\vartheta) \in \mathcal{H}^{2}(P)$, and that the Kunita-Watanabe inequality gives

$$
E\left[\left(\int \eta^{\top} d\langle M\rangle \vartheta\right)_{T}^{*}\right] \leq E\left[\int_{0}^{T}\left|\eta_{s}^{\top} c_{s}^{M} \vartheta_{s}\right| d B_{s}\right] \leq\|\eta\|_{\mathcal{L}^{2}(M)}\|\vartheta\|_{\mathcal{L}^{2}(M)}<\infty
$$

Moreover, using $\int|\vartheta d A|=\int\left|\vartheta^{\top} c^{M} \lambda\right| d B$ and the Cauchy-Schwarz and Doob inequalities allows us to estimate the remaining term by

$$
E\left[\left(\int Z_{-} \vartheta^{\top} d\langle M\rangle \lambda\right)_{T}^{*}\right] \leq E\left[Z_{T}^{*} \int_{0}^{T}\left|\vartheta_{s}^{\top} c_{s}^{M} \lambda_{s}\right| d B_{s}\right] \leq 2\left\|Z_{T}\right\|_{L^{2}(P)}\|\vartheta\|_{\mathcal{L}^{2}(A)} .
$$

Replacing $c_{t}^{M} d B_{t}$ by $d\langle M\rangle_{t}$ and using the estimate

$$
\left(G(\vartheta) Z-\int\left(\eta+Z_{-} \lambda\right)^{\top} c^{M} \vartheta d B\right)_{T}^{*} \leq(Z G(\vartheta))_{T}^{*}+\left(\int \eta^{\top} d\langle M\rangle \vartheta\right)_{T}^{*}+\left(\int Z_{-} \vartheta^{\top} d\langle M\rangle \lambda\right)_{T}^{*}
$$

then shows that the local $P$-martingale in (5.17) has a $P$-integrable supremum.
Using Lemma 5.8 and optimising over $\vartheta$ immediately gives for every $Z \in \mathcal{M}^{2}(P)$

$$
\begin{align*}
\sup _{\vartheta \in \Theta_{S}(C)} E\left[G_{T}(\vartheta) Z_{T}\right] & =\sup _{\vartheta \in \Theta_{S}(C)} E\left[\int_{0}^{T}\left(\eta_{s}+Z_{s-} \lambda_{s}\right)^{\top} c_{s}^{M} \vartheta_{s} d B_{s}\right] \\
& \leq E\left[\int_{0}^{T} \delta\left(c_{s}^{M}\left(\eta_{s}+Z_{s} \lambda_{s}\right) \mid C\right) d B_{s}\right] \tag{5.18}
\end{align*}
$$

by definition of the support function $\delta(\cdot \mid C)$, because each $\vartheta_{s}$ has values in $C$. The next result shows that we even have equality in (5.18). Note that we use the same symbol $\delta$ for support functions in two different Hilbert spaces - $L^{2}(P)$ on the left-hand and $\mathbb{R}^{d}$ on the right-hand side of (5.19).

Lemma 5.9. Suppose that $S$ is in $\mathcal{H}_{\mathrm{loc}}^{2}(P)$ and satisfies the structure condition (SC). For every $Z \in \mathcal{M}^{2}(P)$,

$$
\begin{equation*}
\delta\left(Z_{T} \mid G_{T}\left(\Theta_{S}(C)\right)\right)=\sup _{\vartheta \in \Theta_{S}(C)} E\left[G_{T}(\vartheta) Z_{T}\right]=E\left[\int_{0}^{T} \delta\left(c_{s}^{M}\left(\eta_{s}+Z_{s-} \lambda_{s}\right) \mid C\right) d B_{s}\right] . \tag{5.19}
\end{equation*}
$$

Proof. Without loss of generality, we can assume that $0 \in C(\omega, t)$. Indeed, let $\varphi$ be in $\Theta_{S}(C)$ and set $C^{\prime}=C-\varphi$, which is by Proposition 2.3 a predictable correspondence with $0 \in C^{\prime}(\omega, t)$. Then $\Theta_{S}(C)=\Theta_{S}\left(C^{\prime}\right)+\varphi$ and therefore

$$
\delta\left(Z_{T} \mid G_{T}\left(\Theta_{S}(C)\right)\right)=\delta\left(Z_{T} \mid G_{T}\left(\Theta_{S}\left(C^{\prime}\right)\right)\right)+E\left[Z_{T} G_{T}(\varphi)\right]
$$

and

$$
\begin{aligned}
& E\left[\int_{0}^{T} \delta\left(c_{s}^{M}\left(\eta_{s}+Z_{s-} \lambda_{s}\right) \mid C\right) d B_{s}\right] \\
& =E\left[\int_{0}^{T} \delta\left(c_{s}^{M}\left(\eta_{s}+Z_{s-} \lambda_{s}\right) \mid C^{\prime}\right) d B_{s}+\int_{0}^{T} \varphi_{s}^{\top} c_{s}^{M}\left(\eta_{s}+Z_{s-} \lambda_{s}\right) d B_{s}\right]
\end{aligned}
$$

Since $E\left[Z_{T} G_{T}(\varphi)\right]=E\left[\int_{0}^{T} \varphi_{s}^{\top} c_{s}^{M}\left(\eta_{s}+Z_{s-} \lambda_{s}\right) d B_{s}\right]$ by Lemma 5.8, we obtain that (5.19) holds for $C$ if and only if it holds for $C^{\prime}$.

In view of (5.18), it remains to show that

$$
\sup _{\vartheta \in \Theta_{S}(C)} E\left[G_{T}(\vartheta) Z_{T}\right] \geq E\left[\int_{0}^{T} \delta\left(c_{s}^{M}\left(\eta_{s}+Z_{s-} \lambda_{s}\right) \mid C\right) d B_{s}\right]
$$

To that end, we construct a sequence $\left(\vartheta^{n}\right)$ of $C$-constrained trading strategies such that

$$
\lim _{n \rightarrow \infty} E\left[G_{T}\left(\vartheta^{n}\right) Z_{T}\right]=E\left[\int_{0}^{T} \delta\left(c_{s}^{M}\left(\eta_{s}+Z_{s-} \lambda_{s}\right) \mid C\right) d B_{s}\right]
$$

Define a function $f: \bar{\Omega} \times \mathbb{R}^{d} \rightarrow \mathbb{R}$ by

$$
f((\omega, t), z):=(\eta(\omega, t)+Z(\omega, t-) \lambda(\omega, t))^{\top} c^{M}(\omega, t) y
$$

and for each $n \in \mathbb{N}$ a predictable correspondence $C^{n}$ by

$$
C^{n}(\omega, t):=C(\omega, t) \cap \overline{B_{n}(0)} \subseteq \mathbb{R}^{d}
$$

for $(\omega, t) \in \bar{\Omega}$, where $\overline{B_{n}(0)}$ denotes the closure of the ball of radius $n$ in $\mathbb{R}^{d}$. Note that the $C^{n}$ have convex and compact values and that $0 \in C^{n}(\omega, t)$ for $(\omega, t) \in \bar{\Omega}$ and each $n \in \mathbb{N}$. Moreover, $f(\cdot, z)$ is predictable for $z \in \mathbb{R}^{d}$ and $f((\omega, t), \cdot)$ is continuous for $(\omega, t) \in \bar{\Omega}$, i.e. $f$ is a Carathéodory function. Let $\left\{x^{n, m} \mid m \in \mathbb{N}\right\}$ be a Castaing representation for $C^{n}$ as in Proposition 2.3 and define

$$
g^{n}(\omega, t):=\delta\left(c^{M}(\omega, t)(\eta(\omega, t)+Z(\omega, t-) \lambda(\omega, t)) \mid C^{n}(\omega, t)\right)=\sup _{x \in C^{n}(\omega, t)} f((\omega, t), x)
$$

As $g^{n}(\omega, t)=\sup _{m \in \mathbb{N}} f\left((\omega, t), x^{n, m}(\omega, t)\right)$ by Proposition 2.3, $g^{n}$ is predictable and finitevalued by the compactness of $C^{n}(\omega, t)$. Combining Propositions 2.4 and 2.5 gives that

$$
D^{n}(\omega, t)=\left\{z \in C^{n}(\omega, t) \mid f((\omega, t), z)=g^{n}(\omega, t)\right\}
$$

is a predictable correspondence with non-empty, convex and compact values. Let $y^{n}$ be a predictable selector of $D^{n}$. Then $g^{n}(\omega, t)=f\left((\omega, t), y^{n}(\omega, t)\right)$ and

$$
\delta\left(c^{M}(\omega, t)(\eta(\omega, t)+Z(\omega, t-) \lambda(\omega, t)) \mid C(\omega, t)\right)=\lim _{n \rightarrow \infty} f\left((\omega, t), y^{n}(\omega, t)\right),
$$

where the limit is increasing since $C(\omega, t)=\bigcup_{n \in \mathbb{N}} C^{n}(\omega, t)$. Let $\left(\tau_{m}\right)_{m \in \mathbb{N}}$ be a localising sequence such that $S^{\tau_{m}}$ is in $\mathcal{H}^{2}(P)$. Since $\left|y^{n}(\omega, t)\right| \leq n$ and each $C(\omega, t)$ contains zero, the process $\vartheta^{n}:=y^{n} I_{\llbracket 0, \tau_{n} \rrbracket}$ is in $\Theta_{S}(C)$ for each $n \in \mathbb{N}$. Hence Lemma 5.8 and monotone integration yield

$$
\begin{aligned}
\lim _{n \rightarrow \infty} E\left[G_{T}\left(\vartheta^{n}\right) Z_{T}\right] & =\lim _{n \rightarrow \infty} E\left[\int_{0}^{\tau_{n}}\left(y_{s}^{n}\right)^{\top} c_{s}^{M}\left(\eta_{s}+Z_{s-} \lambda_{s}\right) d B_{s}\right] \\
& =E\left[\int_{0}^{T} \delta\left(c_{s}^{M}\left(\eta_{s}+Z_{s-} \lambda_{s}\right) \mid C\right) d B_{s}\right]
\end{aligned}
$$

which completes the proof.
As Lemma 5.9 relates the support function $\delta\left(\cdot \mid G_{T}\left(\Theta_{S}(C)\right)\right)$ to the expectation of the terminal value of a stochastic process, we are led to reformulate the dual problem (5.8) on the level of stochastic processes in the following way.

## Dual problem (stochastic processes):

$$
\begin{equation*}
\Psi\left(Z_{T}\right)=E\left[\frac{1}{2} Z_{T}^{2}-Z_{T} H+\int_{0}^{T} \delta\left(c_{s}^{M}\left(\eta_{s}+Z_{s-} \lambda_{s}\right) \mid C\right) d B_{s}\right]=\min _{Z \in \mathcal{Y}(y)}! \tag{5.20}
\end{equation*}
$$

where

$$
\begin{aligned}
\mathcal{Y}(y)= & \left\{Z \in \mathcal{M}^{2}(P) \mid Z=Z_{0}+\int \eta d M+R \text { with } Z_{0} \in L^{2}\left(P, \mathcal{F}_{0}\right), \eta \in L^{2}(M),\right. \\
& \left.R \in \mathcal{M}_{0}^{2}(P) \text { strongly } P \text {-orthogonal to } M, \text { and } E\left[Z_{T}\right]=E\left[Z_{0}\right]=y\right\}
\end{aligned}
$$

Remark 5.10. In the Itô process framework of Example 3.13 and if $\mathbb{F}$ is the $P$-augmentation of the filtration generated by $W$, the above dual problem (5.20) for stochastic processes specialises to the dual problem (5.37) considered in [19]; this only needs some adjustments for notation, along the lines of part 2) of Remark 4.2).

Now set $\mathcal{G}_{c}:=G_{T}\left(\Theta_{S}(C)\right)$ so that Lemma 5.9 gives an explicit representation of the support function $\delta\left(\cdot \mid \mathcal{G}_{c}\right)$. Then the functions $\Psi$ in (5.8) and (5.20) coincide, and identifying each $h \in L^{2}(P)$ with the corresponding square-integrable martingale also yields that (5.20) and (5.8) have the same optimal value and therefore the same value function

$$
\begin{align*}
v(y) & =\inf _{Z \in \mathcal{Y}(y)} E\left[\frac{1}{2} Z_{T}^{2}-Z_{T} H+\int_{0}^{T} \delta\left(c_{s}^{M}\left(\eta_{s}+Z_{s-} \lambda_{s}\right) \mid C\right) d B_{s}\right]  \tag{5.21}\\
& =\inf _{h \in \mathcal{D}(y)}\left\{E[V(h)]+\delta\left(h \mid \mathcal{G}_{c}\right)\right\} .
\end{align*}
$$

Moreover, we have the following relation between the primal and dual variables on the level of stochastic processes.

Lemma 5.11. Suppose that $S$ is in $\mathcal{H}_{\mathrm{loc}}^{2}(P)$ and satisfies the structure condition (SC). For every $x \in \mathbb{R}, \vartheta \in \Theta_{S}(C)$ and $Z \in \mathcal{M}^{2}(P)$ with $\delta\left(Z_{T} \mid \mathcal{G}_{c}\right)<\infty$, the process

$$
\left(\left(x+G_{t}(\vartheta)\right) Z_{t}-\int_{0}^{t} \delta\left(c_{s}^{M}\left(\eta_{s}+Z_{s-} \lambda_{s}\right) \mid C\right) d B_{s}\right)_{0 \leq t \leq T}
$$

is a $P$-supermartingale.
Proof. The process $(x+G(\vartheta)) Z-\int_{0}^{t}\left(\eta+Z_{-} \lambda\right)^{\top} c^{M} \vartheta d B$ is a $P$-martingale by Lemma 5.8 and because $Z$ is a $P$-martingale. Moreover, $\int \delta\left(c^{M}\left(\eta+Z_{-} \lambda\right) \mid C\right) d B-\int\left(\eta+Z_{-} \lambda\right)^{\top} c^{M} \vartheta d B$ is adapted and increasing by the definition of the support function $\delta\left(\cdot \mid \mathcal{G}_{c}\right)$, and integrable due to Lemma 5.9 since $\delta\left(Z_{T} \mid \mathcal{G}_{c}\right)<\infty$. Taking the difference gives the result.

Remark 5.12. In our formulation, the process $\left(\int \delta\left(c^{M}\left(\eta+Z_{-} \lambda\right) \mid C\right) d B\right)$ plays a similar role as the upper variation process $A(Q)$ in the optional decomposition of Föllmer and Kramkov in [11]; see also Example 3.2 in [21].

Combining Lemma 5.9 with Lemma 5.11 gives a result for stochastic processes which is analogous to Theorem 5.7.

Theorem 5.13. Assume $\mathcal{E}=\mathcal{E}(N)$ is regular and satisfies $R_{2}(P)$, and that $S \in \mathcal{H}_{\mathrm{loc}}^{2}(P)$ is an $\mathcal{E}$-local martingale. Let $C: \bar{\Omega} \rightarrow 2^{\mathbb{R}^{d}}$ be a predictable correspondence with closed convex values such that $\Theta_{S}(C)$ is non-empty and the projection of $C$ on the predictable range of $S$ is closed, i.e. $\Pi^{S}(\omega, t) C(\omega, t)$ is closed $P_{B}$-a.e. Then:

1) For every $x \in \mathbb{R}$ and $H \in L^{2}(P)$, there exists a solution $\widehat{\vartheta}(x) \in \Theta_{S}(C)$ to

$$
E\left[-\frac{1}{2}\left|x+G_{T}(\vartheta)-H\right|^{2}\right]=\max _{\vartheta \in \Theta_{S}(C)}!
$$

All solutions $\widehat{\vartheta}(x)$ have the same gains process $G(\widehat{\vartheta}(x))$ and satisfy

$$
x+G_{T}(\widehat{\vartheta}(x))=I\left(\widehat{Z}_{T}\right)=-\widehat{Z}_{T}+H,
$$

where $\widehat{Z} \in \mathcal{Y}(\widehat{y}(x))$ and $\widehat{y}(x) \in \mathbb{R}$ are the unique solutions, respectively, to

$$
\Psi\left(Z_{T}\right)=E\left[\frac{1}{2} Z_{T}^{2}-Z_{T} H+\int_{0}^{T} \delta\left(c_{s}^{M}\left(\eta_{s}+Z_{s-} \lambda_{s}\right) \mid C\right) d B_{s}\right]=\min _{Z \in \mathcal{Y}(\hat{y}(x))}!
$$

and

$$
v(y)+x y=\min _{y \in \mathbb{R}}!
$$

2) The value functions $u$ and $v$ are conjugate, i.e.

$$
\begin{aligned}
& u(x)=\inf _{y \in \mathbb{R}}\{v(y)+x y\}, \\
& v(y)=\sup _{x \in \mathbb{R}}\{u(x)-x y\},
\end{aligned}
$$

and continuously differentiable. $u$ is strictly concave and $v$ is strictly convex.
3) The process $(x+G(\widehat{\vartheta}(x))) \widehat{Z}-\int \delta\left(c^{M}\left(\widehat{\eta}+\widehat{Z}_{-} \lambda\right) \mid C\right) d B$ is a $P$-martingale for all solutions $\widehat{\vartheta}(x)$, and $\left(\widehat{\eta}_{s}+\widehat{Z}_{s-} \lambda_{s}\right)^{\top} c_{s}^{M} \widehat{\vartheta}_{s}(x)=\delta\left(c_{s}^{M}\left(\widehat{\eta}_{s}+\widehat{Z}_{s-} \lambda_{s}\right) \mid C\right) P_{B}$-a.e.

Proof. 1) By part 3) of Theorem 3.12, we obtain that $\mathcal{G}_{c}=G_{T}\left(\Theta_{S}(C)\right)$ is a non-empty, closed, convex subset of $L^{2}(P)$. Hence we can apply Theorem 5.7 to obtain unique solutions $\widehat{f}(x) \in \mathcal{C}(x)$ to (5.2) and $\widehat{h}(\widehat{y}(x)) \in \mathcal{D}(\widehat{y}(x))$ to (5.8). Since $\widehat{f}(x)-x$ is in $\mathcal{G}_{c}$, there exists some $\widehat{\vartheta}(x) \in \Theta_{S}(C)$ with $x+G_{T}(\widehat{\vartheta}(x))=\widehat{f}(x)$ which is a solution to (5.1), and since $\widehat{f}(x)$ is unique, this equality must hold for all solutions. As $G(\widehat{\vartheta}(x))$ is an $\mathcal{E}$-martingale, it is uniquely determined by its terminal value and so all solutions $\widehat{\vartheta}(x)$ have this as gains process. Identifying $\widehat{h}(\widehat{y}(x))$ with $\widehat{Z}$ shows that $\widehat{Z}$ solves (5.20); this uses the observation before (5.21) that the functions $\Psi$ in (5.20) and (5.8) coincide due to Lemma 5.9.
2) Since the value functions of (5.1) and (5.2) and (5.20) and (5.8), respectively, coincide, the assertion follows immediately from part 2) of Theorem 5.7.
3) By Lemma 5.11, the process $(x+G(\widehat{\vartheta}(x))) \widehat{Z}-\int \delta\left(c^{M}\left(\widehat{\eta}+\widehat{Z}_{-} \lambda\right) \mid C\right) d B$ is a $P$-supermartingale with initial value $x \widehat{y}(x)$ and final value

$$
\begin{aligned}
& \left(x+G_{T}(\widehat{\vartheta}(x))\right) \widehat{Z}_{T}-\int_{0}^{T} \delta\left(c_{s}^{M}\left(\widehat{\eta}_{s}+\widehat{Z}_{s-} \lambda_{s}\right) \mid C\right) d B_{s} \\
& =\widehat{f}(x) \widehat{h}(\widehat{y}(x))-\int_{0}^{T} \delta\left(c_{s}^{M}\left(\widehat{\eta}_{s}+\widehat{Z}_{s-} \lambda_{s}\right) \mid C\right) d B_{s} .
\end{aligned}
$$

Moreover, Lemma 5.9 shows that

$$
E\left[\int_{0}^{T} \delta\left(c_{s}^{M}\left(\widehat{\eta}_{s}+\widehat{Z}_{s-} \lambda_{s}\right) \mid C\right) d B_{s}\right]=\delta\left(\widehat{Z}_{T} \mid G_{T}\left(\Theta_{S}(C)\right)\right)=\delta\left(\widehat{h}(\widehat{y}(x)) \mid \mathcal{G}_{c}\right)
$$

Hence the first relation in (5.11) implies that the above process has constant expectation and is therefore a $P$-martingale. Combining this with Lemma 5.8 yields that the increasing process $\int \delta\left(c^{M}\left(\widehat{\eta}+\widehat{Z}_{-} \lambda\right) \mid C\right) d B-\int\left(\widehat{\eta}+\widehat{Z}_{-} \lambda\right)^{\top} c^{M} \widehat{\vartheta}(x) d B$ is a martingale null at zero and hence indistinguishable from the zero process. Since the definition of the support function yields $\left(\widehat{\eta}_{s}+\widehat{Z}_{s-} \lambda_{s}\right)^{\top} c_{s}^{M} \widehat{\vartheta}_{s}(x) \leq \delta\left(c_{s}^{M}\left(\widehat{\eta}_{s}+\widehat{Z}_{s-} \lambda_{s}\right) \mid C\right)$, we must have equality $P_{B}$-a.e., and this completes the proof.

### 5.3 Related work

Our approach combines duality techniques and constraints with quadratic optimisation problems and so has connections to several areas, in particular utility maximisation under constraints. Very informally, our results can be viewed as the special case of a state-dependent quadratic utility $U(x, \omega)=-\frac{1}{2}|x-H(\omega)|^{2}$. But they cannot be deduced directly because this "utility function" is not increasing in $x$ and since the duality must be taken in a different setting ( $L^{2}$ instead of $L_{+}^{0}$ ). Let us explain the relations in more detail.

The oldest neoclassical work on utility maximisation under constraints is probably by Cvitanić and Karatzas [5]. In an Itô process setting, they introduced the basic ideas of using convex duality and working with the support function of the constraint set to describe the dual variables and also the dual criterion. The seminal work of Kramkov and Schachermayer [18] extended the duality idea to general semimartingale models without trading constraints. One key idea there was to separate the duality arguments into a static level of random variables and a dynamic level of stochastic processes, like in Sections 5.1 and 5.2. For the static level, this also needed a bipolar theorem in $L_{+}^{0}$. In Karatzas and Žitković [17], general semimartingale models were combined with cone constraints on trading strategies, and the optional decomposition theorem under constraints from [11] was used to obtain the basic duality characterisation of superreplicable consumptioninvestment pairs. In contrast to [5], the support function $\delta$ of the constraint set did not show up explicitly since the latter was a cone; see Remark 5.1. However, [17] obtained a full duality result in the sense that like [18], they could prove the existence of an optimiser for the dual problem and then use that to construct an optimiser for the primal problem. The paper by Mnif and Pham [21] is more general in that it allows American-type as well as convex (not necessarily conic) constraints and does not impose non-negativity for (intermediate values of) the wealth process. The last fact makes it impossible to parametrise strategies by fractions of wealth, and this in turn forces one to use the additive form of the optional decomposition under constraints. Together with the general convex constraints, this leads to an additional term in the objective function for the dual problem. Due to these complications, [21] only obtain a partial (verification) duality result; they show how to construct a primal from a dual optimiser, but do not prove existence of a dual optimiser.

The utility paper closest to our results is probably the one of Pham [22]. It works in finite discrete time with cone constraints (so that, as explained in Remark 5.1, the dual objective function has no explicit extra term), and the key (superreplication) duality rests on the monotonicity of the utility function. But like our approach, it does not impose non-negativity constraints on wealth, and the underlying duality is formulated in an ( $L^{p}, L^{q}$ )-setting.

The second area of related work is mean-variance hedging and mean-variance portfolio selection. Like utility maximisation, this is huge, and we only focus on a small sample of papers. (An attempt at a broader overview can be found in [28]). Duality for mean-variance hedging without constraints is discussed in Hou and Karatzas [12]. An
abstract and static formulation of Markowitz-type problems under cone constraints is given in Sun and Wang [29]; this is similar to Section 5.1, but gives no duality and is considerably simpler since constraints are conic and there is no contingent claim. Labbé and Heunis [19] study quadratic utility maximisation problems in an Itô process model whose completeness is destroyed by having convex constraints on trading strategies. They introduce (in a fairly complicated way, to our mind) a dual problem for certain processes, show that this has a solution and construct from that a solution to the original problem. Via Itô's representation theorem, the last step crucially exploits the completeness of the unconstrained market. The existence proof for the dual optimiser is analogous to our Proposition 5.4, and as in Lemma 5.3, the objective function involves an extra term from the support function of the constraint set. It is a matter of taste whether our results are simpler or more natural than those in [19]; but they are definitely much more general.

Markowitz problems in complete and incomplete Itô process models are also studied in Hu and Zhou [13] and Jin and Zhou [14]. The former has cone constraints on strategies, the latter imposes no short sale constraints (which are also described by cones), and both use (quadratic or linear) BSDEs to obtain a solution. This setup has a lot of extra structure, and the continuity of asset prices simplifies matters considerably. For an extension to general semimartingale models with cone constraints and a more detailed discussion, we refer to forthcoming work in [6].
