RIGIDITY AND STABILITY OF CAFFARELLI'S LOG-CONCAVE PERTURBATION THEOREM

GUIDO DE PHILIPPIS AND ALESSIO FIGALLI

To Nicola Fusco, for his 60th birthday, con affetto e ammirazione.

Abstract. In this note we establish some rigidity and stability results for Caffarelli’s log-concave perturbation theorem. As an application we show that if a 1-log-concave measure has almost the same Poincaré constant as the Gaussian measure, then it almost splits off a Gaussian factor.

1. Introduction

Let $\gamma_n$ denote the centered Gaussian measure in $\mathbb{R}^n$, i.e., $\gamma_n = (2\pi)^{-n/2}e^{-|x|^2/2}dx$, and let $\mu$ be a probability measure on $\mathbb{R}^n$. By a classical theorem of Brenier [2], there exists a convex function $\varphi : \mathbb{R}^n \to \mathbb{R}$ such that $T = \nabla \varphi : \mathbb{R}^n \to \mathbb{R}^n$ transports $\gamma_n$ onto $\mu$, i.e., $T_\sharp \gamma_n = \mu$, or equivalently

$$\int h \circ T \, d\gamma_n = \int h \, d\mu$$

for all continuous and bounded functions $h \in C_b(\mathbb{R}^n)$.

In the sequel we will refer to $T$ as the Brenier map from $\gamma_n$ to $\mu$.

In [4, 5] Caffarelli proved that if $\mu$ is “more log-concave” than $\gamma_n$, then $T$ is 1-Lipschitz, that is, all the eigenvalues of $D^2 \varphi$ are bounded from above by 1. Here is the exact statement:

Theorem 1.1 (Caffarelli). Let $\gamma_n$ be the Gaussian measure in $\mathbb{R}^n$, and let $\mu = e^{-V} \, dx$ be a probability measure satisfying $D^2 V \geq \text{Id}_n$. Consider the Brenier map $T = \nabla \varphi$ from $\gamma_n$ to $\mu$. Then $T$ is 1-Lipschitz. Equivalently, $0 \leq D^2 \varphi(x) \leq \text{Id}_n$ for a.e. $x$.

This theorem allows one to show that optimal constants in several functional inequalities are extremized by the Gaussian measure. More precisely, let $F, G, H, L, J$ be continuous functions on $\mathbb{R}$ and assume that $F, G, H, J$ are nonnegative, and that $H$ and $J$ are increasing. For $\ell \in \mathbb{R}_+$ let

$$\lambda(\mu, \ell) := \inf \left\{ \frac{H\left( \int |\nabla u| \, d\mu \right)}{F\left( \int G(u) \, d\mu \right)} : \, u \in \text{Lip}(\mathbb{R}^n), \int L(u) \, d\mu = \ell \right\}.$$  \hfill (1.1)

Then

$$\lambda(\gamma_n, \ell) \leq \lambda(\mu, \ell).$$  \hfill (1.2)

Indeed, given a function $u$ admissible in the variational formulation for $\mu$, we set $v := u \circ T$ and note that, since $T_\sharp \gamma_n = \mu$,

$$\int K(v) \, d\gamma_n = \int K(u \circ T) \, d\gamma_n = \int K(u) \, d\mu$$

for $K = G, L$.

In particular, this implies that $v$ is admissible in the variational formulation for $\gamma_n$. Also, thanks to Caffarelli’s Theorem,

$$|\nabla v| \leq |\nabla u| \circ T \, |\nabla T| \leq |\nabla u| \circ T,$$
Our first main result states that if \( |\nabla (1.3) \inf \) that

\[ H \left( \int J(|\nabla u|) \, d\gamma_n \right) \leq H \left( \int J(|\nabla u|) \circ T \, d\gamma_n \right) = H \left( \int J(|\nabla u|) \, d\mu \right). \]

Thanks to these formulas, (1.2) follows easily.

Note that the classical Poincaré and Log-Sobolev inequalities fall in the above general framework. For instance, choosing \( H(t) = F(t) = L(t) = t, \ell = 0, \) and \( J(t) = F(t) = |t|^p \) with \( p \geq 1, \) we deduce that

\[
\inf \left\{ \frac{\int |\nabla u|^p \, d\mu}{\int |u|^p \, d\mu} : u \in \text{Lip}(\mathbb{R}^n), \int u \, d\mu = 0 \right\}
\geq \inf \left\{ \frac{\int |\nabla u|^p \, d\gamma_n}{\int |u|^p \, d\gamma_n} : u \in \text{Lip}(\mathbb{R}^n), \int u \, d\gamma_n = 0 \right\}.
\]

Two questions that naturally arise from the above considerations are:

- **Rigidity:** What can be said about \( \mu \) when \( \lambda(\mu, \ell) = \lambda(\gamma_n, \ell) \)?
- **Stability:** What can be said about \( \mu \) when \( \lambda(\mu, \ell) \approx \lambda(\gamma_n, \ell) \)?

Looking at the above proof, these two questions can usually be reduced to the study of the corresponding ones concerning the optimal map \( T \) in Theorem 1.1 (here \( |A| \) denotes the operator norm of a matrix \( A \)).

- **Rigidity:** What can be said about \( \mu \) when \( |\nabla T(x)| = 1 \) for a.e. \( x \)?
- **Stability:** What can be said about \( \mu \) when \( |\nabla T(x)| \approx 1 \) (in suitable sense)?

Our first main result states that if \( |\nabla T(x)| = 1 \) for a.e. \( x \) then \( \mu \) “splits off” a Gaussian factor. More precisely, it splits off as many Gaussian factors as the number of eigenvalues of \( \nabla T = D^2 \varphi \) that are equal to 1. In the following statement and in the sequel, given \( p \in \mathbb{R}^k \) we denote by \( \gamma_{p,k} \) the Gaussian measure in \( \mathbb{R}^k \) with barycenter \( p \), that is, \( \gamma_{p,k} = (2\pi)^{-k/2}e^{-|x-p|^2/2} \, dx \).

**Theorem 1.2 (Rigidity).** Let \( \gamma_n \) be the Gaussian measure in \( \mathbb{R}^n \), and let \( \mu = e^{-V} \, dx \) be a probability measure with \( D^2 V \geq \text{Id}_n \). Consider the Brenier map \( T = \nabla \varphi \) from \( \gamma_n \) to \( \mu \), and let

\[
0 \leq \lambda_1(D^2 \varphi(x)) \leq \cdots \leq \lambda_n(D^2 \varphi(x)) \leq 1
\]

be the eigenvalues of the matrix \( D^2 \varphi(x) \). If \( \lambda_{n-k+1}(D^2 \varphi(x)) = 1 \) for a.e. \( x \) then \( \mu = \gamma_{p,k} \otimes e^{-W(x')} \, dx' \), where \( W : \mathbb{R}^{n-k} \to \mathbb{R} \) satisfies \( D^2 W \geq \text{Id}_{n-k} \).

Our second main result is a quantitative version of the above theorem. Before stating it, let us recall that, given two probability measures \( \mu, \nu \in \mathcal{P}(\mathbb{R}^n) \), the 1-Wasserstein distance between them is defined as

\[
W_1(\mu, \nu) := \inf \left\{ \int |x-y| \, d\sigma(x, y) : \sigma \in \mathcal{P}(\mathbb{R}^n \times \mathbb{R}^n) \text{ such that } (\text{pr}_1)_\sigma = \mu, (\text{pr}_2)_\sigma = \nu \right\},
\]

where \( \text{pr}_1 \) (resp. \( \text{pr}_2 \)) is the projection of \( \mathbb{R}^n \times \mathbb{R}^n \) onto the first (resp. second) factor. Our stability result is formulated in terms of the \( W_1 \)-distance between probability measure as this distance natural comes out from our strategy of proof. Our result could also be proved with other notions of distances metrizing the weak topology (for instance, any Wasserstein distance \( W_p \)), as well as stronger notion of distances (such as the total variation), but we shall not investigate this here.
**Theorem 1.3** (Stability). Let \( \gamma_n \) be the Gaussian measure in \( \mathbb{R}^n \) and let \( \mu = e^{-V} \, dx \) be a probability measure with \( D^2 V \geq \text{Id}_n \). Consider the Brenier map \( T = \nabla \varphi \) from \( \gamma_n \) to \( \mu \), and let

\[
0 \leq \lambda_1(D^2 \varphi(x)) \leq \cdots \leq \lambda_n(D^2 \varphi(x)) \leq 1
\]

be the eigenvalues of \( D^2 \varphi(x) \). Let \( \varepsilon \in (0, 1) \) and assume that

\[
1 - \varepsilon \leq \int \lambda_{n-k+1}(D^2 \varphi(x)) \, d\gamma_n(x) \leq 1.
\]

Then there exists a probability measure \( \nu = \gamma_{p,k} \otimes e^{-W(x')} \, dx' \), with \( W : \mathbb{R}^{n-k} \to \mathbb{R} \) satisfying \( D^2 W \geq \text{Id}_{n-k} \), such that

\[
W_1(\mu, \nu) \lesssim \frac{1}{|\log \varepsilon|^{1/4}}.
\]

In the above statement, and in the rest of the note, we are employing the following notation:

\[
X \lesssim Y^{\beta} \quad \text{if} \quad X \leq C(n, \alpha) Y^\alpha \quad \text{for all} \quad \alpha < \beta.
\]

Analogously,

\[
X \gtrsim Y^{\beta} \quad \text{if} \quad C(n, \alpha) X \geq Y^\alpha \quad \text{for all} \quad \alpha < \beta.
\]

**Remark 1.4.** We do not expect the stability estimate in the previous theorem to be sharp. In particular, in dimension 1 an elementary argument (but completely specific to the one dimensional case) gives a linear control in \( \varepsilon \). Indeed, assuming (up to translating \( \mu \)) that

\[
\int x \, d\mu = 0,
\]

set \( \psi(x) := x^2/2 - \varphi(x) \). Then, since \( \psi'' = (x - T)' > 0 \), our assumption can be rewritten as

\[
\int |(x - T)'| \, d\gamma_1 = \int \psi'' \, d\gamma_1 \leq \varepsilon.
\]

Also, since \( T \# \gamma_1 = \mu \), (1.6) yields

\[
\int T(x) \, d\gamma_1 = 0 = \int x \, d\gamma_1.
\]

Hence, by the \( L^1 \)-Poincaré inequality for the Gaussian measure we obtain

\[
W_1(\mu, \gamma_1) \leq \int |x - y| \, d\sigma_T(x, y) = \int |x - T(x)| \, d\gamma_1 \leq C \int |(x - T)'| \, d\gamma_1 \leq C \varepsilon,
\]

where \( \sigma_T := (\text{Id} \times T) \# \gamma_1 \).

As explained above, Theorems 1.2 and 1.3 can be applied to study the structure of 1-log-concave measures (i.e., measures of the form \( e^{-V} \, dx \) with \( D^2 V \geq \text{Id}_n \)) that almost achieve equality in (1.2). To simplify the presentation and emphasize the main ideas, we limit ourselves to a particular instance of (1.1), namely the optimal constant in the \( L^2 \)-Poincaré inequality for \( \mu \):

\[
\lambda_\mu := \inf \left\{ \frac{\int |\nabla u|^2 \, d\mu}{\int u^2 \, d\mu} : \quad u \in \text{Lip}(\mathbb{R}^n), \quad \int u \, d\mu = 0 \right\}.
\]
It is well-known that $\lambda_n = 1$ and that $\{u_i(x) = x_i\}_{1 \leq i \leq n}$ are the corresponding minimizers. In particular it follows by (1.3) that, for every 1-log-concave measure $\mu$,

$$\int u^2 \, d\mu \leq \int |\nabla u|^2 \, d\mu$$

for all $u \in \text{Lip}(\mathbb{R}^n)$ with $\int u \, d\mu = 0$.

As a consequence of Theorems 1.2 and 1.3 we have:

**Theorem 1.5.** Let $\mu = e^{-V} \, dx$ be a probability measure with $D^2 V \geq \text{Id}_n$, and assume there exist $k$ functions $\{u_i\}_{1 \leq i \leq k} \subset W^{1,2}(\mathbb{R}^n, \mu)$, $k \leq n$, such that

$$\int u_i \, d\mu = 0, \quad \int u_i^2 \, d\mu = 1, \quad \int \nabla u_i \cdot \nabla u_j \, d\mu = 0 \quad \forall i \neq j,$$

and

$$\int |\nabla u_i|^2 \, d\mu \leq 1 + \varepsilon$$

for some $\varepsilon > 0$. Then there exists a probability measure $\nu = \gamma_{p,k} \otimes e^{-W(x')} \, dx'$, with $W : \mathbb{R}^{n-k} \to \mathbb{R}$ satisfying $D^2 W \geq \text{Id}_{n-k}$, such that

$$W_1(\mu, \nu) \lesssim \frac{1}{|\log \varepsilon|^{1/4}}.$$

In particular, if there exist $n$ orthogonal functions $\{u_i\}_{1 \leq i \leq n}$ that attain the equality in (1.7) then $\mu = \gamma_{n,p}$.

We conclude this introduction recalling that the rigidity version of the above theorem (i.e., the case $\varepsilon = 0$) has already been proved by Cheng and Zho in [6, Theorem 2] with completely different techniques.

### 2. Proof of Theorem 1.2

To prove Theorem 1.2, we first recall the following classical estimate due to Alexandrov (see for instance [8, Theorem 2.2.4 and Example 2.1.2(1)] for a proof):

**Lemma 2.1.** Let $\Omega$ be an open bounded convex set, and let $u : \Omega \to \mathbb{R}$ be a $C^{1,1}$ convex function such that $u = 0$ on $\partial \Omega$. Then there exists a dimensional constant $C_n > 0$ such that

$$|u(x)|^n \leq C_n \text{diam}(\Omega)^{n-1} \text{dist}(x, \partial \Omega) \int_{\Omega} \det D^2 u \quad \forall x \in \Omega.$$

**Proof of Theorem 1.2.** Set $\psi(x) := |x|^2/2 - \varphi(x)$ and note that, as a consequence of Theorem 1.1, $\psi : \mathbb{R}^n \to \mathbb{R}$ is a $C^{1,1}$ convex function with $0 \leq D^2 \psi \leq \text{Id}$. Also, our assumption implies that

$$\lambda_1(D^2 \psi(x)) = \ldots = \lambda_k(D^2 \psi(x)) = 0 \quad \text{for a.e. } x \in \mathbb{R}^d.$$

We are going to show that $\psi$ depends only on $n - k$ variables. As we shall show later, this will immediately imply the desired conclusion. In order to prove the above claim, we note it is enough to prove it for $k = 1$, since then one can argue recursively on $\mathbb{R}^{n-1}$ and so on.

Note that (2.1) implies that

$$\det D^2 \psi = 0.$$

Up to translate $\mu$ we can subtract a linear function to $\psi$ and assume without loss of generality that $\psi(x) \geq \psi(0) = 0$.
Consider the convex set $\Sigma := \{ \psi = 0 \}$. We claim that $\Sigma$ contains a line. Indeed, if not, this set would contain an exposed point $\bar{x}$. Up to a rotation, we can assume that $\bar{x} = a e_1$ with $a \geq 0$. Also, since $\bar{x}$ is an exposed point,

$$\Sigma \subset \{ x_1 \leq a \} \quad \text{and} \quad \Sigma \cap \{ x_1 = a \} = \{ \bar{x} \}.$$  

Hence, by convexity of $\Sigma$, the set $\Sigma \cap \{ x_1 \geq -1 \}$ is compact.

Consider the affine function

$$\ell_\eta(x) := \eta(x + 1), \quad \eta > 0 \text{ small},$$

and define $\Sigma_\eta := \{ \psi \leq \ell_\eta \}$. Note that, as $\eta \to 0$, the sets $\Sigma_\eta$ converge in the Hausdorff distance to the compact set $\Sigma \cap \{ x_1 \geq -1 \}$. In particular, this implies that $\Sigma_\eta$ is bounded for $\eta$ sufficiently small.

We now apply Lemma 2.1 to the convex function $\psi - \ell_\eta$ inside $\Sigma_\eta$, and it follows by (2.2) that (note that $D^2 \ell_\eta \equiv 0$)

$$|\psi(x) - \ell_\eta(x)|^n \leq C_n (\text{diam}(\Sigma_\eta))^n \int_{\Sigma_\eta} \det D^2 \psi = 0 \quad \forall x \in \Sigma_\eta.$$  

In particular this implies that $\psi(0) = \ell_\eta(0) = \eta$, a contradiction to the fact that $\psi(0) = 0$.

Hence, we proved that $\{ \psi = 0 \}$ contains a line, say $\mathbb{R} e_1$. Consider now a point $x \in \mathbb{R}^n$. Then, by convexity of $\psi$,

$$\psi(x + \nabla \psi(x) \cdot (se_1 - x)) \leq \psi(se_1) = 0 \quad \forall s \in \mathbb{R},$$

and by letting $s \to \pm \infty$ we deduce that $\partial \psi(x) = \nabla \psi(x) \cdot e_1 = 0$. Since $x$ was arbitrary, this means that $\partial \psi \equiv 0$, hence $\psi(x) = \psi(0, x')$, $x' \in \mathbb{R}^{n-1}$.

Going back to $\varphi$, this proves that

$$T(x) = (x_1, x' - \nabla \psi(x')),$$

and because $\mu = T_\# \gamma_n$ we immediately deduce that $\mu = \gamma_1 \otimes \mu_1$ where $\mu_1 := (\text{Id}_{n-1} - \nabla \psi)_\# \gamma_{n-1}$.

Finally, to deduce that $\mu_1 = e^{-W} dx'$ with $D^2 W \geq \text{Id}_{n-1}$ we observe that $\mu_1 = (\pi')_\# \mu$ where $\pi' : \mathbb{R}^n \to \mathbb{R}^{n-1}$ is the projection given by $\pi'(x_1, x') := x'$. Hence, the result is a consequence of the fact that 1-log-concavity is preserved when taking marginals, see [1, Theorem 4.3] or [9, Theorem 3.8].

\section{Proof of Theorem 1.3}

To prove Theorem 1.3, we first recall a basic properties of convex sets (see for instance [3, Lemma 2] for a proof).

\textbf{Lemma 3.1.} Given $S$ an open bounded convex set in $\mathbb{R}^n$ with barycenter at 0, let $E$ denote an ellipsoid of minimal volume with center 0 and containing $S$. Then there exists a dimensional constant $\kappa_n > 0$ such that $\kappa_n E \subset S$.

Thanks to this result, we can prove the following simple geometric lemma:

\textbf{Lemma 3.2.} Let $\kappa_n$ be as in Lemma 3.1, set $c_n := \kappa_n/2$, and consider $S \subset \mathbb{R}^n$ an open convex set with barycenter at 0. Assume that $S \subset B_R$ and $\partial S \cap \partial B_R \neq \emptyset$. Then there exists a unit vector $v \in S^{n-1}$ such that $\pm c_n Rv \in S$.  

□
Proof. By scaling we can assume that $R = 1$.

Let $v \in \partial S \cap \partial B_1$, and consider the ellipsoid $E$ provided by Lemma 3.1. Since $v \in \mathcal{E}$ and $E$ is symmetric with respect to the origin, also $-v \in \mathcal{E}$. Hence

$$\pm c_n v \in c_n \mathcal{E} \subset \kappa_n E \subset S,$$

as desired. \hfill \Box

In order to complete the proof of Theorem 1.3 we recall the following geometric result, see [3, Lemma 1].

**Lemma 3.3.** Let $\psi : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ be a nonnegative convex function with $\psi(0) = 0$. Assume that $\psi$ is finite in a neighbourhood of 0 and that the graph of $\psi$ does not contain lines. Then there exists $p \in \mathbb{R}^n$ such that the open convex set

$$S_1 := \{x : \psi(x) \leq p \cdot x + 1\}$$

is nonempty, bounded, and with barycenter at 0.

**Proof of Theorem 1.3.** As in the proof of Theorem 1.2 we set $\psi := |x|^2/2 - \varphi$. Then, inequality (1.4) gives

$$\int \lambda_k(D^2\psi) \, d\gamma_n \leq \varepsilon.$$ 

(3.1)

Up to subtract a linear function (i.e., substituting $\mu$ with one of its translation, which does not affect the conclusion of the theorem) we can assume that $\psi(x) \geq \psi(0) = 0$, therefore $\nabla \psi(0) = \nabla \varphi(0) = 0$. Since $(\nabla \varphi)_# \gamma_n = \mu$ and $\|D^2 \varphi\|_{\infty} \leq 1$, these conditions imply that

$$\int |x| \, d\mu(x) = \int |\nabla \varphi(x)| \, d\gamma_n(x) = \int |\nabla \varphi(x) - \nabla \varphi(0)| \, d\gamma_n(x) \leq \int |x| \, d\gamma_n(x) \leq C_n.$$ 

In particular

$$W_1(\mu, \gamma) \leq W_1(\mu, \delta_0) + W_1(\delta_0, \gamma) \leq C_n.$$ 

This proves that (1.5) holds true with $\nu = \gamma_n$ and with a constant $C \approx |\log \varepsilon_0|^{1/4}$ whenever $\varepsilon \geq \varepsilon_0$. Hence, when showing the validity of (1.5), we can safely assume that $\varepsilon \leq \varepsilon_0(n) \ll 1$. Furthermore, we can assume that the graph of $\psi$ does not contain lines (otherwise, by the proof of Theorem 1.2, we would deduce that $\mu$ splits a Gaussian factor, and we could simply repeat the argument in $\mathbb{R}^{n-1}$).

Thus we can apply Lemma 3.3 to deduce the existence of a slope $p \in \mathbb{R}^n$ such that

$$S_1 = \{x \in \mathbb{R}^n : \psi(x) < p \cdot x + 1\}$$

is nonempty, bounded, and with barycenter at 0. Applying Lemma 2.1 to the convex function $\tilde{\psi}(x) := \psi(x) - p \cdot x - 1$ inside the set $S_1$, we get (note that $D^2 \tilde{\psi} = D^2 \psi$)

$$1 \leq \left(-\min_{S_1} \tilde{\psi}\right)^n \leq C_n(\text{diam}(S_1))^n \int_{S_1} \det D^2 \psi.$$ 

(3.2)

Consider now the smallest radius $R > 0$ such that $S_1 \subset B_R$ (note that $R < +\infty$ since $S_1$ is bounded). Since $\gamma_n \geq c_n e^{-R^2/2}$ in $B_R$ and $A_i(D^2 \psi) \leq 1$ for all $i = 1, \ldots, n$, (3.1) implies that

$$\int_{B_R} \det D^2 \psi \leq C_n e^{R^2/2} \varepsilon.$$
Hence, using (3.2), since \( \text{diam}(S_1) \leq 2R \) we get

\[
1 \leq C_n R^n e^{R^2/2}\varepsilon
\]

which yields

(3.3) \[
R \gtrsim |\log \varepsilon|^{1/2+}.
\]

Now, up to a rotation and by Lemma 3.2, we can assume that

\[
\pm c_n Re_1 \in S_1.
\]

Consider \( 1 \ll \rho \ll R^{1/2} \) to be chosen. Since \( S_1 \subset B_R \) and \( \psi \geq 0 \) we get that \(|p| \leq 1/R\), therefore \( \psi \leq 2 \) on \( S_1 \subset B_R \). Hence

\[
2 \geq \psi(z) \geq \psi(x) + \langle \nabla \psi(x), z - x \rangle \geq \langle \nabla \psi(x), z - x \rangle \quad \forall z \in S_1, x \in B_\rho.
\]

Thus, since \( |\nabla \psi| \leq \rho \) in \( B_\rho \) (by \( \|D^2 \psi\|_{L^\infty(\mathbb{R}^n)} \leq 1 \) and \( |\nabla \psi(0)| = 0 \)), choosing \( z = \pm c_n Re_1 \) we get

(3.4) \[
|\partial_1 \psi| \leq \frac{C_n \rho^2}{R} \quad \text{inside } B_\rho.
\]

Consider now \( \bar{x}_1 \in [-1,1] \) (to be fixed later) and define \( \psi_1(x') := \psi(\bar{x}_1, x') \) with \( x' \in \mathbb{R}^{n-1} \). Integrating (3.4) with respect to \( x_1 \) inside \( B_{\rho/2} \), we get

\[
|\psi - \psi_1| \leq \frac{C_n \rho^3}{R} \quad \text{inside } B_{\rho/2}.
\]

Thus, using the interpolation inequality

\[
\|\nabla \psi - \nabla \psi_1\|_{L^\infty(B_{\rho/4})} \leq C_n \|\psi - \psi_1\|_{L^\infty(B_{\rho/2})} \|D^2 \psi - D^2 \psi_1\|_{L^\infty(B_{\rho/2})}
\]

and recalling that \( \|D^2 \psi\|_{L^\infty(\mathbb{R}^n)} \leq 1 \) (hence \( \|D^2 \psi_1\|_{L^\infty(\mathbb{R}^{n-1})} \leq 1 \)), we get

\[
|\nabla \psi - \nabla \psi_1| \leq \frac{C_n \rho^{3/2}}{R^{1/2}} \quad \text{inside } B_{\rho/4}.
\]

If \( k = 1 \) we stop here, otherwise we notice that (3.1) implies that

\[
\int_\mathbb{R} \int_{\mathbb{R}^{n-1}} d\gamma_1(x_1) \int_{\mathbb{R}^{n-1}} \text{det} D^2_{x', x'} \psi(x, x') d\gamma_{n-1}(x') \leq \int_\mathbb{R} \int_{\mathbb{R}^{n-1}} \lambda_2(D^2 \psi)(x_1, x') d\gamma_{n-1}(x') \leq \varepsilon,
\]

where we used that

\[
\lambda_1(D^2 \psi|_{\{0\} \times \mathbb{R}^{n-1}} \leq \lambda_2(D^2 \psi)
\]

and that (since \( 0 \leq D^2 \psi \leq \text{Id}_n \))

\[
\text{det} D^2_{x', x'} \psi(x_1, x') \leq \lambda_1(D^2 \psi|_{\{0\} \times \mathbb{R}^{n-1}}).
\]

Hence, by Fubini’s Theorem, there exists \( \bar{x}_1 \in [-1,1] \) such that \( \psi_1(x') = \psi(\bar{x}_1, x') \) satisfies

\[
\int_{\mathbb{R}^{n-1}} \text{det} D^2 \psi_1 d\gamma_{n-1}(x) \leq C_n \varepsilon.
\]

\[1\text{This inequality follows from the general fact that, given } A \in \mathbb{R}^{n \times n} \text{ symmetric matrix and } W \subset \mathbb{R}^n \text{ a } k\text{-dimensional vector space,}
\]

\[
\lambda_1(A|_W) = \min_{v \in W} \frac{A v \cdot v}{|v|^2} \geq \max_{W' \subset \mathbb{R}^n \text{ k-dim}} \min_{W'' \subset \mathbb{R}^n \text{ k-dim}} \frac{A v \cdot v}{|v|^2} = \lambda_{n-k+1}(A).
\]
This allows us to repeat the argument above in \( \mathbb{R}^{n-1} \) with
\[
\tilde{\psi}^1(x') := \psi_1(x') - \nabla_{x'} \psi_1(0) \cdot x' - \psi_1(0)
\]
in place of \( \psi \), and up to a rotation we deduce that
\[
|\nabla \tilde{\psi}_1 - \nabla \psi_2| \leq C_n \frac{p'^{3/2}}{R^{1/2}} \quad \text{inside } B_{\rho/4},
\]
where \( \psi_2(x'') := \psi_1(\bar{x}_2, x'') \), where \( \bar{x}_2 \in [-1, 1] \) is arbitrary. By triangle inequality, this yields
\[
|\nabla \psi + p' - \nabla \psi_2| \leq C_n \frac{p'^{3/2}}{R^{1/2}} \quad \text{inside } B_{\rho/4},
\]
where \( p' = -(0, \nabla_{x'} \psi(\bar{x}_2, 0)) \). Note that, since \( |\bar{x}_2| \leq 1 \), \( \nabla \psi(0) = 0 \), and \( \|D^2 \psi\|_{\infty} \leq 1 \), we have \( |p| \leq 1 \). Iterating this argument \( k \) times, we conclude that
\[
|\nabla \psi + \bar{p} - \nabla \psi_k| \leq C_n \frac{p_k^{3/2}}{R^{1/2}} \quad \text{inside } B_{\rho/4}
\]
where \( \bar{p} = (p, p'') \in \mathbb{R}^k \times \mathbb{R}^{n-k} = \mathbb{R}^n \) with \( |\bar{p}| \leq C_n \),
\[
\psi_k(y) := \psi(\bar{x}_1, \ldots, \bar{x}_k, y), \quad y \in \mathbb{R}^{n-k},
\]
and \( \bar{x}_i \in [-1, 1] \). Recalling that \( \nabla \varphi = x - \nabla \psi \), we have proved that
\[
T(x) = \nabla \varphi(x) = (x_1 + p_1, \ldots, x_k + p_k, S(y) + p'') + Q(x),
\]
where \( Q := -(\nabla \psi - \nabla \psi_k + \bar{p}) \) satisfies
\[
\|Q\|_{L^\infty(B_{\rho})} \leq C_n \frac{p_k^{3/2}}{R^{1/2}} \quad \text{and} \quad |Q(x)| \leq C_n (1 + |x|)
\]
(in the second bound we used that \( T(0) = \nabla \varphi(0) = 0 \), \( |p| \leq C_n \), and \( T \) is 1-Lipschitz). Hence, if we set \( \nu := (S + p'')_{\#} \gamma_{n-k} \), we have
\[
W_1(\mu, \gamma_{p,k} \otimes \nu) \leq \int |Q| \, d\gamma_{n} \leq C_n \frac{p_k^{3/2}}{R^{1/2}} + C_n \int_{\mathbb{R}^{n} \setminus B_{\rho}} |x| \, d\gamma_{n} = C_n \frac{p_k^{3/2}}{R^{1/2}} + C_n p^n e^{-\nu^2/2},
\]
so, by choosing \( \rho := (\log R)^{1/2} \), we get
\[
W_1(\mu, \gamma_{p,k} \otimes \nu) \lesssim \frac{1}{R^{1/2 +}}.
\]
Consider now \( \pi_k : \mathbb{R}^n \to \mathbb{R}^n \) and \( \tilde{\pi}_{n-k} : \mathbb{R}^n \to \mathbb{R}^{n-k} \) the orthogonal projection onto the first \( k \) and the last \( n - k \) coordinates, respectively. Define \( \mu_1 := (\pi_k)_{\#}(e^{-V} \, dx) \), \( \mu_2 := (\tilde{\pi}_{n-k})_{\#}(e^{-V} \, dx) \), and note that these are 1-log-concave measures in \( \mathbb{R}^k \) and \( \mathbb{R}^{n-k} \) respectively (see [1, Theorem 4.3] or [9, Theorem 3.8]). In particular \( \mu_2 = e^{-W} \) with \( D^2 W \geq \text{Id}_{n-k} \). Moreover, since \( W_1 \) decreases under orthogonal projection,
\[
W_1(\mu_2, \nu) = W_1((\tilde{\pi}_{n-k})_{\#} \mu_1, (\tilde{\pi}_{n-k})_{\#}(\gamma_{p,k} \otimes \nu)) \leq W_1(\mu, \gamma_{p,k} \otimes \nu) \lesssim \frac{1}{R^{1/2 +}},
\]
thus
\[
W_1(\mu, \gamma_{p,k} \otimes \mu_2) \leq W_1(\mu, \gamma_{p,k} \otimes \nu) + W_1(\gamma_{p,k} \otimes \nu, \gamma_{p,k} \otimes \mu_2)
\]
\[
\leq W_1(\mu, \gamma_{p,k} \otimes \nu) + W_1(\nu, \mu_2) \lesssim \frac{1}{R^{1/2 -}}.
\]
where we used the elementary fact that $W_1(\gamma_{p,k} \otimes \nu, \gamma_{p,k} \otimes \mu_2) \leq W_1(\nu, \mu_2)$. Recalling (3.3), this proves that

$$W_1(\mu, \gamma_{p,k} \otimes \nu) \lesssim \frac{1}{|\log \varepsilon|^{1/4}},$$

concluding the proof. \hfill \Box

### 4. Proof of Theorem 1.5

**Proof of Theorem 1.5.** As in the proof of Theorem 1.3, it is enough to prove the result when $\varepsilon \leq \varepsilon_0 \ll 1$.

Let $\{u_i\}_{1 \leq i \leq k}$ be as in the statement, and set $v_i := u_i \circ T$, where $T = \nabla \varphi : \mathbb{R}^n \to \mathbb{R}^n$ is the Brenier map from $\gamma_n$ to $\mu$. Note that since $T\# \gamma_n = \mu$,

$$\int v_i \, d\gamma_n = \int u_i \circ T \, d\gamma_n = \int u_i \, d\mu = 0. $$

Also, since $|\nabla T| \leq 1$ and by our assumption on $u_i$,

$$\int |\nabla v_i|^2 \, d\gamma_n \leq \int |\nabla u_i|^2 \circ T \, d\gamma_n = \int |\nabla u_i|^2 \, d\mu \leq (1 + \varepsilon) \int u_i^2 \, d\mu = (1 + \varepsilon) \int v_i^2 \, d\gamma_n \leq (1 + \varepsilon) \int |\nabla v_i|^2 \, d\gamma_n,$$

where the last inequality follows from the Poincaré inequality for $\gamma_n$ applied to $v_i$. Since

$$\int |\nabla u_i|^2 \, d\mu \leq 1 + \varepsilon,$$

this proves that

$$0 \leq \int \left( |\nabla u_i|^2 \circ T - |\nabla v_i|^2 \right) \, d\gamma_n \leq \varepsilon \int |\nabla v_i|^2 \, d\mu \leq \varepsilon (1 + \varepsilon).$$

Moreover, by Theorem 1.1, $\nabla T = D^2 \varphi$ is a symmetric matrix satisfying $0 \leq \nabla T \leq \text{Id}_n$, therefore $(\text{Id} - \nabla T)^2 \leq \text{Id} - (\nabla T)^2$. Hence, since $\nabla v_i = \nabla T \cdot \nabla u_i \circ T$, it follows by (4.1) that

$$\int |\nabla u_i \circ T - \nabla v_i|^2 \, d\gamma_n = \int |(\text{Id}_n - \nabla T) \cdot \nabla u_i \circ T|^2 \, d\gamma_n$$

$$= \int |(\text{Id}_n - (\nabla T)^2)[\nabla u_i \circ T, \nabla u_i \circ T]| \, d\gamma_n$$

$$\leq \int \left| \text{Id}_n - (\nabla T)^2 \right| |\nabla u_i \circ T, \nabla u_i \circ T| \, d\gamma_n$$

$$= \int \left( |\nabla u_i|^2 \circ T - |\nabla v_i|^2 \right) \, d\gamma_n \leq 2\varepsilon,$$

where, given a matrix $A$ and a vector $v$, we have used the notation $A[v, v]$ for $Av \cdot v$. In particular, recalling the orthogonality constraint $\int \nabla u_i \cdot \nabla u_j \, d\mu = 0$, we deduce that

$$\int \nabla v_i \cdot \nabla v_j \, d\gamma_n = O(\sqrt{\varepsilon}).$$

In addition, if we set

$$f_i(x) := \frac{\nabla u_i \circ T(x)}{|\nabla u_i \circ T(x)|},$$
then, using again that $|\nabla T| \leq 1$,

$$
\int |\nabla (u_i \circ T)|^2 \left( 1 - |\nabla T \cdot f_i|^2 \right) \, d\gamma \leq \int |\nabla u_i|^2 \circ T \left( 1 - |\nabla T \cdot f_i|^2 \right) \, d\gamma_n \leq 2\varepsilon.
$$

(4.4)

Now, for $j \in \mathbb{N}$, let $H_j : \mathbb{R} \to \mathbb{R}$ be the one dimensional Hermite polynomial of degree $j$:

$$
H_j(t) = \frac{(-1)^j}{\sqrt{j!}} e^{t^2/2} \left( \frac{d}{dt} \right)^j e^{-t^2/2}
$$

see [7, Section 9.2]. It is well known (see for instance [7, Theorem 9.7]) that for $J = (j_1, \ldots, j_n) \in \mathbb{N}^n$ the functions

$$
H_j(x_1, \ldots, x_n) := H_{j_1}(x_1)H_{j_2}(x_2) \cdots H_{j_n}(x_n)
$$

form a Hilbert basis of $L^2(\mathbb{R}^n, \gamma_n)$. Hence, since $\alpha_0 = \int v_i \, d\gamma_n = 0$, we can write

$$
v_i = \sum_{J \in \mathbb{N}^n \setminus \{0\}} \alpha_J^i H_J.
$$

By elementary computations (see for instance [7, Proposition 9.3]), we get

$$
1 = \int v_i^2 \, d\gamma_n = \sum_{J \in \mathbb{N}^n \setminus \{0\}} (\alpha_J^i)^2, \quad \int |\nabla v_i|^2 \, d\gamma_n = \sum_{J \in \mathbb{N}^n \setminus \{0\}} |J|(\alpha_J^i)^2,
$$

where $|J| = \sum_{m=1}^n j_m$. Hence, combining the above equations with the bound $\int |\nabla v_i|^2 \, d\gamma_n \leq (1 + \varepsilon)$, we obtain

$$
\varepsilon \geq \int |\nabla v_i|^2 \, d\gamma_n - \int v_i^2 \, d\gamma_n = \sum_{J \in \mathbb{N}^n \setminus \{0\}, |J| \geq 2} |J| - 1 \cdot (\alpha_J^i)^2 \geq \frac{1}{2} \sum_{J \in \mathbb{N}^n \setminus \{0\}, |J| \geq 2} |J|(\alpha_J^i)^2.
$$

Recalling that the first Hermite polynomials are just linear functions (since $H_1(t) = t$), using the notation

$$
\alpha_J^i := \alpha_J^i \quad \text{with } J = e_j \in \mathbb{N}^n
$$

we deduce that

$$
v_i(x) = \sum_{j=1}^n \alpha_J^j x_j + z(x), \quad \text{with } \|z\|_{W^{1,2}(\mathbb{R}^n, \gamma_n)}^2 = O(\varepsilon).
$$

In particular, if we define the vector

$$
V_i := \sum_{j=1}^n \alpha_J^j e_j \in \mathbb{R}^n,
$$

and we recall that $\int |\nabla v_i|^2 \, d\gamma_n = 1 + O(\varepsilon)$ and the almost orthogonality relation (4.3), we infer that $|V_i| = 1 + O(\varepsilon)$ and $|V_i \cdot V_l| = O(\sqrt{\varepsilon})$ for all $i \neq l \in \{1, \ldots, k\}$.

Hence, up to a rotation, we can assume that $|V_i - e_i| = O(\sqrt{\varepsilon})$ for all $i = 1, \ldots, k$, and (4.2) yields

$$
\int |\nabla (u_i \circ T) - e_i|^2 \, d\gamma_n \leq C \varepsilon.
$$

(4.5)

Since $0 \leq 1 - |\nabla T \cdot f_i|^2 \leq 1$, it follows by (4.4) and (4.5) that

$$
\int \left( 1 - |\nabla T \cdot f_i|^2 \right) \, d\gamma_n \leq 2 \int \left( |\nabla (u_i \circ T)|^2 + |\nabla (u_i \circ T) - e_i|^2 \right) \left( 1 - |\nabla T \cdot f_i|^2 \right) \, d\gamma_n \leq C \varepsilon.
$$

(4.6)
Set $w_i := \nabla u_i \circ T$ so that $f_i = \frac{w_i}{|w_i|}$. We note that, since all the eigenvalues of $\nabla T = D^2 \varphi$ are bounded by 1, given $\delta \ll 1$ the following holds: whenever
\[
|\nabla T \cdot w_i - e_i| \leq \delta \quad \text{and} \quad |\nabla T \cdot f_i| \geq 1 - \delta
\]
then $|w_i| = 1 + O(\delta)$. In particular,
\[
|\nabla T \cdot f_i - e_i| \leq C \delta.
\]
Hence, if $\delta \leq \delta_0$ where $\delta_0$ is a small geometric constant, this implies that the vectors $f_i$ are a basis of $\mathbb{R}^k$, and
\[
\nabla T|_{\text{span}(f_1, \ldots, f_k)} \geq (1 - C_0 \delta) \text{Id}_k
\]
for some dimensional constant $C_0$. Defining $\psi(x) := |x|^2/2 - \varphi(x)$, this proves that
\[
(4.7) \quad \left\{ x : \sum_{i=1}^k \left| \nabla T(x) \cdot w_i(x) - e_i \right| + \left( 1 - |\nabla T(x) \cdot f_i(x)| \right) \leq \delta \right\} \subset \left\{ x : \lambda_{n-k+1}(D^2 \psi(x)) \leq C_0 \delta \right\}
\]
for all $0 < \delta \leq \delta_0$. Hence, by the layer-cake formula, (4.5), and (4.6),
\[
\int_{\left\{ \lambda_{n-k+1}(D^2 \psi) \leq C_0 \delta_0 \right\}} \lambda_{n-k+1}(D^2 \psi) \, d\gamma_n = C_0 \int_0^{\delta_0} \gamma_n(\left\{ \lambda_{n-k+1}(D^2 \psi) > C_0 s \right\}) \, ds
\]
\[
\leq C_0 \int_0^{\delta_0} \gamma_n \left( \sum_{i=1}^k \left| \nabla T(x) \cdot w_i(x) - e_i \right| + \left( 1 - |\nabla T(x) \cdot f_i(x)| \right) > s \right) \right\} ds
\]
\[
\leq C_0 \sum_{i=1}^k \int \left( |\nabla T \cdot w_i - e_i| + \left( 1 - |\nabla T \cdot f_i| \right) \right) d\gamma_n \leq C \sqrt{\varepsilon}.
\]
On the other hand, it follows by (4.7) that
\[
\left\{ x : \lambda_{n-k+1}(D^2 \psi(x)) > C_0 \delta \right\}
\subset \bigcup_{i=1}^k \left\{ x : |\nabla T(x) \cdot w_i(x) - e_i| > \delta/2k \right\} \cup \left\{ x : \left( 1 - |\nabla T(x) \cdot f_i(x)| \right) > \delta/2k \right\}.
\]
Thus, (4.5), (4.6), and Chebyshev’s inequality yield
\[
(4.9) \quad \gamma_n \left( \left\{ \lambda_{n-k+1}(D^2 \psi) > C_0 \delta_0 \right\} \right) \leq \sum_{i=1}^k \gamma_n \left( \left\{ |\nabla T \cdot w_i - e_i| > \delta_0/2k \right\} \right)
\]
\[
+ \sum_{i=1}^k \gamma_n \left( \left\{ 1 - |\nabla T \cdot f_i| > \delta_0/2k \right\} \right) \leq C \frac{\varepsilon}{\delta_0^2}.
\]
Hence, since $\delta_0$ is a small but fixed geometric constant, combining (4.8) and (4.9), and recalling that $\lambda_{n-k+1}(D^2 \psi) \leq 1$, we obtain
\[
\int \lambda_{n-k+1}(D^2 \psi) \, d\gamma_n \leq C \sqrt{\varepsilon}.
\]
This implies that (1.4) holds with $C \sqrt{\varepsilon}$ in place of $\varepsilon$, and the result follows by Theorem 1.3.  \[\square\]
