## Structure of the talk

- Introduction: motivation & main questions
- Meta distributions: formal definition & some properties
- Preliminary results
  - review of useful definitions
  - consequences of relaxing some of the underlying assumptions
- Setting up the framework & assumptions
- Key steps to compute the limit set
- Main result
- Sensitivity of the limit shape
- Concluding remarks & further questions

Image: A Image: A

## Motivation: Why multivariate extremes?

#### Quantitative Risk Management (QRM):

• a new field of research

#### Key ingredients:

- Regulatory framework for financial institutions: Basel Accords and Solvency II
- Quantile-based risk measures: Value-at-Risk (VaR) and Expected Shortfall (ES)
- Extremes matter: high quantiles ( $\alpha \in \{99\%, 99.9\%, 99.97\%\}$ )
- Dependence matters: risk aggregation, diversification/ concentration
- Dimensionality matters: high-dimensional portfolios

#### Conclusion:

• Extremal behaviour in multivariate models

▲圖 ▶ ▲ 国 ▶ ▲ 国 ▶ …

Motivation: A few examples

Some concrete underlying models:

- multivariate normal (KMV model)
- multivariate Student t
- and refinements
  - (mixture of) Gaussian copula(s) with exponential marginals (Li model)
  - meta-t with normal marginals
  - etc.

 $\longrightarrow$  The subprime crisis questions some of these developments/models

・ 回 ト ・ ヨ ト ・ ヨ ト

## Why meta distributions?

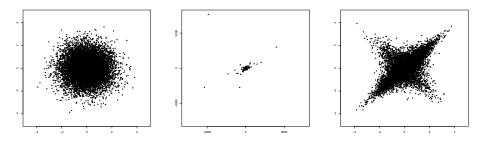

- Asymptotic independence of coordinatewise maxima as a shortcoming of the multivariate Gaussian model
- Go beyond normality by introducing stronger tail dependence while preserving normal marginals
- A typical example:
  - Start with a multivariate Student *t* distribution (tail dependence and heavy tails)
  - Transform each coordinate so that the new distribution has normal marginals (light tails)
  - The new distribution is referred to as meta distribution with normal marginals based on the original *t* distribution (tail dependence and light tails)

Extremes and asymptotic shape of sample clouds and level sets

- Global shape of sample clouds vs. classical EVT of coordinatewise maxima
- The limit shape describes the relation between maximal observations in different directions
- Relation of the shape of density level sets and the shape of risk regions to the conditional laws (cf. *Barbe, P. (2003)*)

- 4 同 6 4 日 6 4 日 6

## Examples of sample clouds

standard normal

elliptic Cauchy with dispersion matrix  $\Sigma = \begin{pmatrix} 5/4 & 3/4 \\ 3/4 & 5/4 \end{pmatrix}$ 

meta-Cauchy with normal marginals

## Main questions of this talk

 The shape of level sets {g > c} for the meta density g depends on the level c.

Does the shape converge as  $c \downarrow 0$ ?

What is the limit shape of the level sets?

- Can sample clouds from the meta density g be scaled to converge? What is the limit shape of scaled sample clouds?
- Properties of the limit set?

- 4 目 ト - 4 日 ト - 4 日 ト

#### Definition (Meta distribution)

- Random vector **Z** in  $\mathbb{R}^d$  with df **F** and continuous marginals  $F_i$ , i = 1, ..., d
- $\textit{G}_1, \ldots, \textit{G}_d$  : continuous df's on  $\mathbb{R},$  strictly increasing on  $I_i = \{0 < G_i < 1\}$
- Define transformation:

 $K(x_1,...,x_d) = (K_1(x_1),...,K_d(x_d)), \quad K_i(s) = F_i^{-1}(G_i(s)), \quad i = 1,...,d$ 

- The df G = F 

   K is the meta distribution (with marginals G<sub>i</sub>) based on original df F
- **X** is said to be a meta vector for **Z** (with marginals  $G_i$ ) if  $\mathbf{Z} \stackrel{d}{=} K(\mathbf{X})$

 The coordinatewise map K = K<sub>1</sub> ⊗ · · · ⊗ K<sub>d</sub> which maps x = (x<sub>1</sub>,...,x<sub>d</sub>) ∈ I = I<sub>1</sub> × · · · × I<sub>d</sub> into the vector z = (K<sub>1</sub>(x<sub>1</sub>),...,K<sub>d</sub>(x<sub>d</sub>)) is called the meta transformation

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ ● □ ● ○ ○ ○

## Meta density

#### Proposition

#### lf

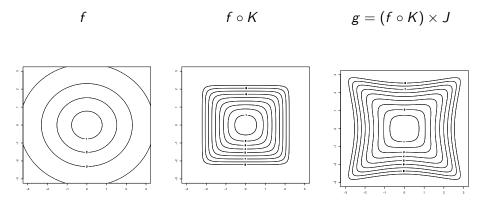

- Original vector Z has a density, f
- Marginals of meta distribution have densities, g<sub>i</sub>

then the meta distribution has a density, g, and g is of the form

$$g(\mathbf{x}) = f(\mathcal{K}(\mathbf{x})) \prod_{i=1}^{d} \frac{g_i(x_i)}{f_i(z_i)} \qquad z_i = \mathcal{K}_i(x_i), \ x_i \in I_i = \{0 < G_i < 1\}$$

## Useful definitions

#### Definition (weak asymptotic equivalence)

 $\tilde{h}(\mathbf{x}) {\asymp} h(\mathbf{x})$  for  $\|\mathbf{x}\| \to \infty$  if

- $\tilde{h}$  and h are positive eventually
- both  $\frac{\tilde{h}(\mathbf{x})}{h(\mathbf{x})}$  and  $\frac{h(\mathbf{x})}{\tilde{h}(\mathbf{x})}$  are bounded outside a compact set

< □ > < @ > < 注 > < 注 > ... 注

## Useful definitions

#### Definition (univariate regular variation)

A measurable function h on  $(0, \infty)$  is regularly varying at  $\infty$  with index  $\rho$  (written  $h \in RV_{\rho}$ ) if for x > 0

$$\lim_{t\to\infty}\frac{h(tx)}{h(t)}=x^{\rho}$$

#### Question:

What is the effect on the meta density when changing the original density into a density which is (weakly) asymptotic to it?

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

## On asymptotic behaviour of multivariate functions

#### Proposition

Assume:

- $F \& \tilde{F}$ : multivariate df's with continuous marginals  $F_i \& \tilde{F}_i, i = 1, ..., d$
- $G_1, \ldots, G_d$  are strictly increasing df's on  $\mathbb R$
- $F_i(-t)\in RV_{
  ho^-}$  and  $1-F_i(t)\in RV_{
  ho^+}$  with  $ho^\pm < 0$
- $ilde{F}_i(-t) \sim F_i(-t)$  and  $1 ilde{F}_i(t) \sim 1 F_i(t)$  as  $t o \infty$

Then the meta transformations satisfy:

$$\frac{\|\tilde{K}(\mathbf{x}) - K(\mathbf{x})\|}{1 + \|K(\mathbf{x})\|} \to 0 \qquad \|\mathbf{x}\| \to \infty$$

(日) (圖) (E) (E) (E)

#### Proposition

Assume:

- Densities f and  $\tilde{f}$  are continuous and positive outside a bounded set
- Marginal densities  $f_i$  and  $\tilde{f}_i$  are continuous

- 
$$\widetilde{f}(\mathsf{z}) \asymp f(\mathsf{z})$$
 for  $\|\mathsf{z}\| o \infty$ 

- $f(\mathbf{z}_n + \mathbf{p}_n) \asymp f(\mathbf{z}_n)$  if  $\|\mathbf{z}_n\| \to \infty$  and  $\|\mathbf{p}_n\| / \|\mathbf{z}_n\| \to 0$
- Meta densities g and  $\tilde{g}$  have all marginals equal to a continuous positive symmetric density  $g_d$

lf

• 
$$F_i(-t) \in RV_{
ho^-}$$
 and  $1 - F_i(t) \in RV_{
ho^+}$  with  $ho^\pm < 0$ 

• 
$$ilde{F}_i(-t) \sim F_i(-t)$$
 and  $1 - ilde{F}_i(t) \sim 1 - F_i(t)$  as  $t o \infty$ 

then the meta densities  $\widetilde{g}(\mathbf{x})$  and  $g(\mathbf{x})$  satisfy:  $\widetilde{g}(\mathbf{x}) \asymp g(\mathbf{x}) = \|\mathbf{x}\| \to \infty$ 

(日) (圖) (E) (E) (E)

## Framework & assumptions

A class of densities with level sets of the same shape (1/2)

- Set *D*: bounded convex open set containing the origin
- Gauge function of D: a unique function  $n_D$  with the properties

$$\{n_D < 1\} = D$$
  $n_D(r\mathbf{z}) = rn_D(\mathbf{z})$   $r > 0, \ \mathbf{z} \in \mathbb{R}^d$ 

- $f_0$ : continuous, strictly decreasing positive function on  $[0,\infty)$
- Then f : z → f<sub>0</sub>(n<sub>D</sub>(z)) is unimodal with convex level sets all of the same shape
- Assume f is a probability density

- 4 目 ト - 4 日 ト - 4 日 ト

A class of densities with level sets of the same shape (2/2)

#### Note:

- If  $f_0 \in RV_{-(\lambda+d)}$  then
  - (i) f integrable
  - (ii) marginal densities  $f_i \in RV_{-(\lambda+1)}$
- (i) & (ii) remain true if
  - $f(\mathbf{z}) \sim f_0(n_D(\mathbf{z}))$  for  $\|\mathbf{z}\| 
    ightarrow \infty$
  - D is a bounded star-shaped open set with continuous boundary

ヘロト 人間ト 人間ト 人間ト

#### Definition (Standard set-up)

- f: a continuous density on  $\mathbb{R}^d$ , positive outside a bounded set
- $f(\mathbf{z}) \sim f_0(n_D(\mathbf{z}))$  for  $\|\mathbf{z}\| \to \infty$ , where
  - f<sub>0</sub>: continuous, strictly decreasing
  - $f_0 \in RV_{-(\lambda+d)}$
  - D: bounded star-shaped open set containing the origin, with continuous boundary
- meta density g with marginal densities gd satisfying
  - g<sub>d</sub>: continuous, positive, symmetric
  - $g_d \sim e^{-\psi}$ , a von Mises function; i.e.

 $\psi'(s)>0, \quad \psi'(s) o\infty, \quad (1/\psi')'(s) o 0 \qquad s o\infty$

• Additional condition:

$$\psi \in RV_{\theta}, \quad \theta > 0 \qquad (\bigstar)$$

- Remarks:
  - (★) is necessary to have a limit shape
  - ( $\bigstar$ ) is satisfied for normal, Laplace, Weibull densities and densities of the form  $g_d(s) \sim as^b e^{-ps^{\theta}}$ ,  $s \to \infty$ ,  $a, p, \theta > 0$

< ロ > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

## Derivation of the limit set

Main idea: The limit set may be described as the level set of a continuous function obtained from the meta density by scaling and power norming

## Limit set

- Under the standard set-up & (★), level sets of g may be scaled to converge to a limit set, E
- There exists a compact set E such that

$$\frac{g(s\mathbf{u})}{g(s\mathbf{1})} \to \begin{cases} \infty & \mathbf{u} \in \mathsf{int}(E) \\ 0 & \mathbf{u} \in E^c \end{cases} \qquad s \to \infty$$

• For a proper limit function for the quotient, use power norming to dampen exponential decrease by constructing functions

$$\left(rac{g(s\mathbf{u})}{g(s\mathbf{1})}
ight)^{\epsilon(s)} \qquad ext{where} \quad \epsilon(s) 
ightarrow \mathbf{0} \qquad s 
ightarrow \infty$$

 Exponent ε(s) may be chosen so that χ<sub>s</sub> converges to a continuous function uniformly on compact sets in R<sup>d</sup>

▲圖 ▶ ▲ 国 ▶ ▲ 国 ▶

## Limit set

• Write  $g = e^{-\gamma}$ 

Then

$$\left(\frac{g(s\mathbf{u})}{g(s\mathbf{1})}\right)^{\epsilon(s)} = \exp\left\{\left(\gamma(s\mathbf{1}) - \gamma(s\mathbf{u})\right)\frac{\epsilon(s)}{\epsilon(s)}\right\}$$

• We show

$$\chi_{s}(\mathbf{u}) := \frac{\gamma(s\mathbf{1}) - \gamma(s\mathbf{u})}{\psi(s)/\lambda} \to \chi(\mathbf{u}) \qquad s \to \infty, \ \mathbf{u} \neq \mathbf{0}$$

That is,

$$\gamma(s\mathbf{1}) - \gamma(s\mathbf{u}) \sim \chi(\mathbf{u}) \psi(s) / \lambda \qquad s \to \infty$$

• Hence

$$\operatorname{int}(E) = \{\chi > 0\}$$
  $\partial E = \{\chi = 0\}$ 

Next step: determine the limit function  $\chi$ 

Э

## The limit function $\chi$

- First assume f(z) = f<sub>0</sub>(||z||<sub>∞</sub>) for a continuous strictly decreasing function f<sub>0</sub> ∈ RV<sub>-(λ+d)</sub>
- Under the standard set-up &  $(\bigstar)$ , it can be shown for  $v = \|\mathbf{u}\|_{\infty} > 0$

 $\chi_{s}(\mathbf{u}) \rightarrow \chi(\mathbf{u}) = |u_{1}|^{\theta} + \dots + |u_{d}|^{\theta} + \lambda - (\lambda + d)v^{\theta} \qquad s \rightarrow \infty$ 

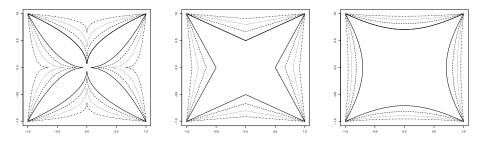

- Convergence is uniform on  $\Pi_r \setminus \epsilon B$  for any  $r \ge 1$  and  $\epsilon > 0$ , where  $\Pi_r = \{ \mathbf{x} \mid |x_i| \le x_d \le r \}$  (upside down pyramid)
- Hence, the limit set is given by

$$E := E_{\lambda,\theta} := \{ \mathbf{u} \in \mathbb{R}^d \setminus \{ \mathbf{0} \} \mid |u_1|^{\theta} + \dots + |u_d|^{\theta} + \lambda \ge (\lambda + d) \|\mathbf{u}\|_{\infty}^{\theta} \} \quad (\clubsuit$$

(日) (圖) (E) (E) (E)

### Examples of limit sets

$$\theta = 0.1$$
  $\theta = 1$   $\theta = 2$ 

Legend:  $\lambda = 1$  (solid),  $\lambda = 2$  (dashed),  $\lambda = 4$  (dotted),  $\lambda = 10$  (dotdash)

## Limit sets for sample clouds

We show:

- For sample clouds from the meta density g there is a limit shape
- If
- $X_1$ ,  $X_2$ ,... is a random sample from meta density g
- Scaling factor  $r_n$  is chosen s.t.  $ng(r_n \mathbf{1}) \to 1$

then the scaled sample cloud  $N_n = {X_1/r_n, ..., X_n/r_n}$  roughly fills out the limit set E

イロト 不得 トイヨト イヨト

#### Definition (convergence of measures and sample clouds onto a set)

- E: a compact set in  $\mathbb{R}^d$
- μ<sub>n</sub>: finite measures

#### We say $\mu_n$ converge onto E if

- $\mu_n(\mathbf{p} + \epsilon B) \rightarrow \infty$  for any  $\epsilon$ -ball centered in a point  $\mathbf{p} \in E$
- $\mu_n(U^c) \rightarrow 0$  for all open sets U containing E

The finite point processes  $N_n = {\mathbf{X}_1/r_n, \dots, \mathbf{X}_n/r_n}$  converge onto E if

- $\mathbb{P}\{N_n(\mathbf{p}+\epsilon B)>m\} \to 1$   $m>1, \epsilon>0, \mathbf{p}\in E$
- $\mathbb{P}{N_n(U^c) > 0} \rightarrow 0$  for open sets U containing E

▲ロト ▲圖 ▶ ▲ 画 ▶ ▲ 画 ▶ ● の Q @

#### Proposition (criterion for convergence of sample clouds)

- $N_n$ : an *n*-point sample cloud from a probability distribution  $\pi_n$  on  $\mathbb{R}^d$
- $N_n$  converges onto E if the mean measures  $\mu_n = n\pi_n$  converge onto E

イロト 不得 トイヨト イヨト

## Main result

#### Theorem

Let:

- $f \& g_d$  satisfy assumptions of the standard set-up  $\& (\bigstar)$
- g: meta density with marginals  $g_d$  based on original density f
- $r_n > 0$  satisfies  $g_d(r_n) \sim 1/n$
- $E = E_{\lambda,\theta}$ : closed subset of  $C = [-1,1]^d$  defined in  $(\clubsuit)$

Then:

- Level sets  $\{g \ge 1/n\}$  scaled by  $r_n$  converge to E
- For any sequence of independent observations X<sub>n</sub> from meta density g, the scaled sample clouds N<sub>n</sub> = {X<sub>1</sub>/r<sub>n</sub>,..., X<sub>n</sub>/r<sub>n</sub>} converge onto E

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ ● □ ● ○ ○ ○

# How sensitive is the limit shape to small perturbations of the original density?

Exploring sensitivity of the limit shape (1/4)

#### Example

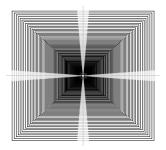

- Assume f: a density on  $\mathbb{R}^2$  with square levels sets and Student t marginals  $f_d(t) \sim 1/2t^2$ ,  $t \to \infty$
- Delete the mass on a strip T = {(x, y) | |x| ≤ y/log y, y ≥ e}, and on sets obtained by reflections (x, y) → (y, x), (-x, -y), (-y, -x)
- Compensate for the lost mass by increasing *f* in compact neighbourhood of the origin
- We obtain a new density  $\tilde{f}$  ; assume  $\tilde{f}_d(t) \sim 1/2t^2, \quad t 
  ightarrow \infty$
- Choose  $K_d(s) = e^s$ ,  $s \ge s_0$
- Then  $g_d(s) \sim e^{-s}/2, \quad s \to \infty$

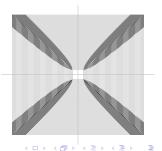

# Exploring sensitivity of the limit shape (2/4) Example (cont'd)

- Edge of a square:  $[-e^n, e^n] \times \{e^n\} \stackrel{\mathrm{K}^{-1}}{\mapsto} [-n, n] \times \{n\}$
- Strip T on the edge:  $[-e^n/n, e^n/n] \times \{e^n\} \stackrel{\mathrm{K}^{-1}}{\mapsto} [-n + \log n, n \log n] \times \{n\}$

Squares  $C_n = e^n C$  in **z**-space

Squares  $C_n = nC$  in **x**-space

Exploring sensitivity of the limit shape (3/4)

### Example (cont'd)

We have:

- $\tilde{f}$  close to f such that  $\tilde{g}$  vanishes everywhere except on a thin strip around the diagonals
- Scaled sample clouds from  $\tilde{g}$  converge onto the cross consisting of the two diagonals of the standard square  $C = [-1, 1]^2$
- Scaled sample clouds from  $\tilde{f}$  and f converge to the same Poisson point process with intensity  $h(\mathbf{w}) = 1/\|\mathbf{w}\|_{\infty}^3$
- Hence
  - Coordinatewise maxima from  $ilde{f}$  and f have the same limit  $\, \Rightarrow \,$
  - Coordinatewise maxima from  $\tilde{g}$  and g also have the same limit
  - But drastic change in the shape of the limit sets for  $\tilde{g}$  and g

## Exploring sensitivity of the limit shape (4/4)

#### Theorem

- F: a df on  $[0,\infty)^d$  with marginals  $F_d$  continuous, strictly increasing
- $1 F_d \in RV_{-\lambda}$
- Suppose dF does not charge set  $T = T_{\epsilon} \setminus \epsilon^{-1}B$  for some  $\epsilon > 0$ , where

$$T_{\epsilon} = \{ \mathbf{z} = (z_1, \dots, z_d) \mid \frac{\min_i |z_i|}{r} < \frac{\epsilon}{\log r}, \ r = \|\mathbf{z}\|_2 > 1 + 1/\epsilon \}$$

- G: meta df with marginals  $G_d$  continuous, strictly increasing on  $[0,\infty)$
- $1-G_d\sim e^{-\psi}$ ,  $\psi\in RV_ heta$ , heta>0
- Scaling factor  $r_n$ :  $1 G_d(r_n) = 1/n$

Then measures  $d\mu_n(\mathbf{u}) = ndG(r_n\mathbf{u})$  converge onto the set  $E = \{t\mathbf{1} \mid 0 \le t \le 1\}$  in  $[0,\infty)^d$ 

## Concluding remarks

- Original and meta densities have the same copula, yet a relation between the shapes of their level sets is lost in the limit
- The limit set is unchanged if we replace the original density f by a density which is weakly asymptotic to f
- Sensitivity of the limit shape may be radical due to even slight perturbations of the original density
- The limit shape gives a very rough picture
- Next step: closer look at the edge of the scaled sample clouds under a more refined scaling
