

(iii) Geometric interpretation

minimize $\|A\vec{x} - \vec{b}\|_2 \leadsto A\vec{x} - \vec{b}$ is normal
to $Im(A)$
(Hence normal equations)

Ex.: (2) Linear model no slides

However, it turns out that solving the normal equations can be problematic, i.e. ill-conditioned

(a small change in \vec{b} can lead to a large change in \vec{x})

Therefore the (following) orthogonal decomposition method is preferred
