**Abstract.** We prove a generic vanishing theorem for twists of perverse sheaves on a commutative algebraic group $G$ over a finite field. Using this tool, we construct a tannakian category with convolution on $G$ as tensor operation. Using Deligne’s Riemann Hypothesis, we show how this leads to equidistribution theorems for discrete Fourier transforms of trace functions of perverse sheaves on $G$, generalizing the work of Katz in the case of the multiplicative group. We give some concrete examples of applications of these results.

Preface

The Fourier transform, and the whole collection of its variants whose study is summarized under the heading of “harmonic analysis”, is one of the most important tools of mathematics. In its many forms, its applications cover the whole range not only of mathematics, but also physics, computer science, chemistry and indeed of all sciences where quantitative tools are applied.

In 1976, P. Deligne observed in a letter to D. Kazhdan (which is reproduced in Appendix D) that the formalism of algebraic geometry, and especially of \(\ell\)-adic cohomology and the derived category of \(\ell\)-adic sheaves, provided a new “geometric” form of the Fourier transform. Instead of the familiar integral formula

\[
\hat{f}(y) = \int_{\mathbb{R}} f(x) e^{-2i\pi xy} dx
\]

associating to a function \(f\) (say \(f : \mathbb{R} \to \mathbb{C}\) in the Schwartz space) its Fourier transform \(\hat{f}\), Deligne’s version takes as input an \(\ell\)-adic constructible sheaf \(M\), or a complex of those, on the one-dimensional affine space over a finite field \(k\) of characteristic \(p\), and outputs a Fourier transform \(\hat{M}\) which is of the same kind.

We note that although the most general and convenient category of input objects \(M\), which we will also call “coefficients”, is given by the formalism of derived categories of \(\ell\)-adic complexes with \(\ell\) prime different from \(p\), there is a simpler definition in the case considered here, where \(M\) can (in almost all cases) be thought of as being a continuous finite-dimensional representation \(\varrho : \text{Gal}(k(T)^{\text{sep}}/k(T)) \to \text{GL}_r(\mathbb{Q}_\ell)\) of the absolute Galois group of the field \(k(T)\) of rational functions on \(k\).

The crucial point for the interpretation of this construction as a Fourier transform is that to each object \(M\) is associated classically a sequence of “trace functions”, which are functions \(t_M(\cdot; k_n) : k_n \to \mathbb{C} \simeq \mathbb{Q}_\ell\) defined on the finite extensions \(k_n\) of \(k\) of degree \(n\), for all integers \(n \geq 1\), and Deligne’s Fourier transform then satisfies

\[
t_{\hat{M}}(y; k_n) = \sum_{x \in k_n} t_M(x; k_n) e^{2i\pi \text{Tr}_{k_n/k}(xy)/p}
\]

Thus, the trace functions of \(\hat{M}\) coincide with the discrete Fourier transforms of those of \(M\).

Deligne’s Fourier transform shares many features with the classical euclidean Fourier transform, once properly interpreted in terms of the coefficients \(M\). For instance:

– it satisfies a form of the Fourier inversion formula

\[
f(x) = \int_{\mathbb{R}} \hat{f}(y) e^{2i\pi xy} dy,
\]

in the sense that applying the (similarly defined) analogue of the inverse Fourier transform to \(\hat{M}\) recovers \(M\).
– it satisfies analogues of the Plancherel formula, which are however rather less obvious: one interpretation is that if the representation $\varrho$ above is irreducible, then so is the representation associated to $\hat{M}$.

– it satisfies a geometric analogue of the fundamental algebraic relation $\hat{f} \ast g = \hat{f} \hat{g}$, which relates the Fourier transform and the convolution product

$$(f \ast g)(x) = \int_{\mathbb{R}} f(y)g(x - y)dy$$

of functions (this property is often taken as the key feature of Fourier analysis and especially Pontryagin duality, see e.g. [13]). Indeed, to two coefficients $M_1$ and $M_2$, another geometric construction associates a third one $M_3$, such that the trace function of $M_3$ is given by

$$t_{M_3}(x; k_n) = \sum_{y \in k_n} t_{M_1}(y; k_n)t_{M_2}(x - y; k_n),$$

the discrete convolution of those of $M_1$ and $M_2$.

– and there is a subtle analogue, due to Laumon, of the stationary phase principle for estimating oscillatory integrals.

There are however also special features related to the geometric nature of trace functions:

– Deligne’s Fourier transform preserves a particularly important subcategory of coefficients, that of perverse sheaves – this extremely important fact has no obvious classical analogue.

– If a coefficient object $M$ is a perverse sheaf, and hence also its transform $\hat{M}$, then one can associate to it a natural intrinsic symmetry group, also called its monodromy group, which is an algebraic group over $\mathbb{Q}_\ell$ (or over $\mathbb{C}$). The definition of this group can be seen as a wide-ranging generalization of that of the Galois group of a polynomial. (In the one-dimensional case, where $\hat{M}$ can be identified, in most cases, with a Galois representation $\varrho$: $\text{Gal}(k(T)^{\text{sep}}/k(T)) \to \text{GL}_r(\mathbb{Q}_\ell)$ as above, the symmetry group is the Zariski-closure of the image of $\varrho$.)

Deligne’s Fourier transform has found a number of very important applications in arithmetic and algebraic geometry, as well as number theory. In the former direction, Laumon [87] used it to obtain a product formula for the epsilon factors of Artin-type L-functions on curves over finite fields. In number theory, Katz used the Fourier transform extensively to study in depth the distribution properties of families of exponential sums, which are obtained as discrete Fourier transforms of simple trace functions (see for instance [61] and [62]); the symmetry group of the Fourier transform $\hat{M}$ plays an essential role here. A prominent example of such sums are the Kloosterman sums

$$\text{Kl}_2(a; p) = \frac{1}{\sqrt{p}} \sum_{x \in \mathbb{F}_p^\times} e \left( \frac{\bar{x} + ax}{p} \right)$$

which are the values of the trace function of the Fourier transforms of a one-dimensional Galois representation, and are omnipresent in modern analytic number theory (here and below, we denote $e(z) = \exp(2\pi iz)$, and $\bar{x}$ is the inverse of $x$ modulo $p$). Results about these and similar sums, which often rely on properties of the $\ell$-adic Fourier transform, have by now become essential in many fundamental results of analytic number theory – some concrete examples, for instance, appear in Zhang’s famous work on bounded gaps between primes [114, Lemma 12], and systematic use of the Fourier transform begins in various papers of Fouvry, Kowalski and Michel (see for instance [37]).
Deligne’s transform is the geometric analogue of the classical euclidean Fourier transform on $\mathbb{R}$ and can be generalized to $n$ variables. But, in recent years, a number of applications have led to questions concerning similar properties of other discrete Fourier transforms, for instance those related to the multiplicative group $k_n^\times$, which are functions on the group of multiplicative characters $\chi: k_n^\times \to \mathbb{Q}_\ell$. The study of the distribution, or average properties, of these sums is outside of the realm of applications of Deligne’s Fourier transform, and cannot be expressed in the usual formalism of algebraic geometry over finite fields.

The fundamental motivation for this book is the search for a definition of the analogue of Deligne’s Fourier transform on an arbitrary commutative algebraic group over a finite field, and for the general theory and applications of this form of harmonic analysis. In particular, we believe that these arithmetic Fourier transforms can be interpreted in the context of much more general arithmetic or geometric avatars of harmonic and functional analysis.

The basic examples of commutative algebraic groups are the multiplicative groups (or tori), and abelian varieties, and these can be combined (together with additive groups) in various ways. The choice of an input object $M$ on such a group $G$ leads to its arithmetic Fourier transforms, which are the functions of the form

$$\hat{t}_M(\chi; k_n) = \sum_{x \in G(k_n)} \chi(x)t_M(x; k_n),$$

defined for any $n \geq 1$, where the parameter $\chi$ ranges over characters of the finite group $G(k_n)$.

The simplest example beyond the additive case is that of $G(k_n) = k_n^\times$, in which case the characters are multiplicative characters of $k_n$. N. Katz, in a striking breakthrough, succeeded a few years ago in finding an interpretation of these arithmetic Fourier transforms in his fundamental book [68]. To do this, Katz exploited the formalism of tannakian categories, and the fact that the convolution product extends to any commutative algebraic group: given coefficients $M_1$ and $M_2$ on $G$, there exists a geometrically-defined object $M_3$ such that their respective trace functions satisfy

$$t_{M_3}(x; k_n) = \sum_{y \in G(k_n)} t_{M_1}(y; k_n)t_{M_2}(xy^{-1}; k_n),$$

for $n \geq 1$ and $x \in G(k_n)$.

Although Katz’s interpretation of the arithmetic Mellin transforms is not fully geometric (there is no analogue of the object $\hat{M}$ which “is” Deligne’s additive Fourier transform for the additive group), Katz shows that it is enough to define a symmetry group for the arithmetic Mellin transform. In combination with another fundamental tool, Deligne’s general form of the Riemann Hypothesis over finite fields [27], this allowed Katz to prove an equidistribution theorem which controls the distributions of arithmetic Mellin transforms. A number of significant applications followed (see, for instance, the paper [74] of Keating and Rudnick, and the work [52] of Hall, Keating and Roditty–Gershon).

One of the main theoretical achievements of this book is the extension of these ideas of Katz to any connected commutative algebraic group. This extension is very far from routine, since certain necessary tools, such as generic cohomological vanishing, or estimates for Betti numbers, which are very elementary in the case considered by Katz were not known previously for groups of dimension at least 2. Indeed, we rely in an essential way on the very recent quantitative sheaf theory due to Sawin [100] (which was partly motivated by this work and drafted in final form jointly with the authors).

For any suitable coefficient object on the group $G$, our construction provides the fundamental invariant of its arithmetic Fourier transform, its intrinsic symmetry group. Combined again with
other tools such as Deligne’s Riemann Hypothesis over finite fields, this is already sufficient to prove a very general form of equidistribution theorem, which encompasses the previously known cases of Deligne and Katz (and in fact sharpens these in certain aspects). In turn, we can use this equidistribution theorem for a number of first applications, including strengthening and simplifying the results of [52]. But there remain also many open questions and problems, both on the theoretical side and on that of applications – we will discuss briefly some of these at the end of this book.

After this preface, the book will continue with a more technical introduction, which contains precise statements of some of the key results and a quick description of some of the crucial points which are involved in the proofs. We then split the remainder of the book in two parts, one containing the main theoretical results, and the other devoted to a variety of applications. These are complemented by appendices recalling important material, and by Appendix D where Deligne’s letter to Kazhdan is reproduced.

A more precise outline of each chapter will be found at the end of the introduction.

Readers with a background in analytic number theory who are not familiar with the theory of trace functions and the underlying geometric objects are invited to first read Appendix E, where we attempt to present them in a concrete and intuitive way.

Acknowledgements

We are particularly thankful to Will Sawin, not only for many insightful comments on parts of this work, but especially for sharing his ideas on the complexity of ℓ-adic sheaves on algebraic varieties, and for allowing us to assist in the final write-up of his work, resulting in the preprint [100].

We thank Thomas Krämer for useful comments concerning some of his papers, especially [82]. We thank Arnaud Beauville for his help with some questions concerning cubic hypersurfaces, especially for the proof of Lemma 12.8. We also thank Sophie Morel for providing us with a proof of Lemma A.15. We thank Florent Jouve for his careful reading of Appendix E; we also thank Jon Keating for his encouragements, and Zeev Rudnick for his constructive criticism, concerning this same appendix.

We thank N. Katz for forwarding to us the notes to his talk [67].

We also thank the organizers of the various seminars where we have been able to present parts of this work over the last two years.

We thank P. Deligne for kindly allowing us to reproduce his letter to Kazhdan in an appendix.
Introduction

1. Statement of results

Since Deligne’s proof of his equidistribution theorem for traces of Frobenius of ℓ-adic local systems on varieties over finite fields [27], it has been known that any family of exponential sums parameterized by an algebraic variety satisfies some form of equidistribution, and that the concrete expression of this equidistribution statement depends on the determination of the geometric monodromy group of the ℓ-adic sheaf that underlies the family of exponential sums.

The best known result of this kind is probably the computation by Katz [61] of these monodromy groups in the case of Kloosterman sums in many variables over finite fields, which are defined for some fixed non-trivial additive character ψ of \( F_q \) and \( a \in F_q^× \) as

\[
Kl_m(a; q) = \frac{(-1)^{m-1}}{q^{(m-1)/2}} \sum_{(x_1, \ldots, x_m) \in \left( F_q^× \right)^m, x_1 \cdots x_m = a} \psi(x_1 + \cdots + x_m).
\]

This computation led him in particular to the proof of the average version of the Sato-Tate law for classical Kloosterman sums, namely the equidistribution of the set \( (Kl_2(a; q))_{a \in F_q^×} \) as \( q \to +\infty \) with respect to the Sato-Tate measure on \([-2, 2]\). Further deep investigations by Katz, especially in his monograph [62], provide a cornucopia of examples of equidistribution statements.

Among other things, this framework allows for the study of exponential sums of the form

\[
S(M, \psi) = \sum_{x \in F_{q^n}} t_M(x; F_{q^n}) \psi(x),
\]

where \( t_M \) is the trace function of a perverse sheaf \( M \) on the additive group \( G_a \) over \( F_q \) and \( \psi \) ranges over characters of \( F_{q^n} \). These sums are the discrete Fourier transform \( \psi \mapsto S(M, \psi) \) of the function \( x \mapsto t_M(x, F_{q^n}) \) on the finite group \( F_{q^n} = G_a(F_{q^n}) \), and the key point is that they are themselves the trace functions of another perverse sheaf on the dual group parameterizing additive characters.

In a more recent conceptual breakthrough, Katz [68] succeeded in proving equidistribution results for families of exponential sums parameterized by multiplicative characters, despite the fact that the set of multiplicative characters of a finite field \( F_q \) does not naturally arise as the set of \( F_q \)-points of an algebraic variety. In analogy with the above, such sums are of the form

\[
S(M, \chi) = \sum_{x \in F_{q^n}^×} t_M(x; F_{q^n}) \chi(x),
\]

except that \( M \) is now a perverse sheaf on the multiplicative group \( G_m \) over \( F_q \) and \( \chi \) ranges over characters of \( F_{q^n}^× \). Katz’s beautiful insight was to replace points of algebraic varieties by fiber functors of tannakian categories as parameter spaces, and produce the groups governing equidistribution by means of the tannakian formalism (see [39] for an accessible survey). Further work of Katz generalized this to elliptic curves [70] and certain abelian varieties (see [70]).
The primary goal of this book is to extend these ideas to exponential sums (arithmetic Fourier transforms) parameterized by the characters of the points of any connected commutative algebraic group over a finite field.

More precisely, let $k$ be a finite field and $\overline{k}$ an algebraic closure of $k$. Let $\ell$ be a prime number different from the characteristic of $k$ and $\overline{\mathbb{Q}}_\ell$ an algebraic closure of the field of $\ell$-adic numbers. Let $G$ be a connected commutative algebraic group over $k$. We denote by $\hat{G}(k_n)$ the group of $\overline{\mathbb{Q}}_\ell$-valued characters of $G(k_n)$ and, for each $\chi \in \hat{G}(k_n)$, by $\mathcal{L}_\chi$ the $\ell$-adic lisse character sheaf of rank one associated to $\chi$ by means of the Lang torsor construction, as briefly recalled in Section 1.5. By perverse sheaves, we always understand $\overline{\mathbb{Q}}_\ell$-perverse sheaves.

In rough outline, we establish the following types of theoretical results:

- We prove generic and stratified vanishing theorems for the cohomology of twists of perverse sheaves on $G$ by the sheaves $\mathcal{L}_\chi$ associated to characters $\chi \in G(k_n)$.
- Using the stratified vanishing theorems, we construct a tannakian category of perverse sheaves on $G$ in which the tensor product is given by the convolution coming from the group law.
- We prove that the tannakian group of a semisimple object $M$ of this category that is pure of weight zero controls the distribution properties of the analogue of the sums above, namely
  \[ S(M, \chi) = \sum_{x \in G(k_n)} t_M(x; k_n) \chi(x), \]
  where $\chi$ ranges over the set $\hat{G}(k_n)$. Under some assumptions on $G$ (e.g., for tori and abelian varieties), we prove the stronger result that the unitary conjugacy classes of which these sums are traces become equidistributed in a maximal compact subgroup of the tannakian group as $n \to +\infty$, as is customary since Deligne’s work.

Once this is done, we provide a number of applications, both of a general nature or for concrete groups and concrete perverse sheaves.

The following statements are special cases of our main results, which we formulate in simplified form in order to make it possible to present self-contained statements at this stage.

**Theorem 1.** Let $M$ be a perverse sheaf on a connected commutative algebraic group $G$ of dimension $d$ over a finite field $k$.

1. (Generic vanishing) The sets
   \[ \mathcal{X}(k_n) = \{ \chi \in \hat{G}(k_n) \mid H^i(G_{\overline{k}}, M \otimes \mathcal{L}_\chi) = 0 \text{ for all } i \neq 0 \]
   \[ \text{and } H^0(G_{\overline{k}}, M \otimes \mathcal{L}_\chi) \text{ is isomorphic to } H^0(G_{\overline{k}}, M \otimes \mathcal{L}_\chi) \} \]
   are generic, in the sense that the estimate
   \[ |\hat{G}(k_n) - \mathcal{X}(k_n)| \ll |k_n|^{d-1} \]
   holds for $n \geq 1$, with an implied constant that only depends on $M$.

2. (Stratified vanishing) For $-d \leq i \leq d$ and $n \geq 1$, the estimate
   \[ \left| \{ \chi \in \hat{G}(k_n) \mid H^i(G_{\overline{k}}, M \otimes \mathcal{L}_\chi) \neq 0 \text{ or } H^i(G_{\overline{k}}, M \otimes \mathcal{L}_\chi) \neq 0 \} \right| \ll |k_n|^{d-i} \]
   holds, with an implied constant that only depends on $M$. 6
The most general vanishing statements that we prove appear as Theorems 2.1 and 2.3. Applications to “stratification” estimates for exponential sums are then given in Chapter 6.

Remark 1. (1) With variations in the definition of generic set of characters, such statements were proved by Katz–Laumon [71] for powers of the additive group, Saibi [99] for unipotent groups, Gabber–Loeser [46] for tori, Weissauer [113] for abelian varieties and Krämer [81] for semiabelian varieties (see Remark 2.2 for more precise references).

(2) In characteristic zero, and especially over the field of complex numbers, theorems of this type have also been proved for abelian and semiabelian varieties by Schnell [103], Bhatt–Scholze–Schnell [7] and Liu–Maxim–Wang [90] (see also [89] for a survey of some applications of such results). Over arbitrary algebraically closed fields, there has also been recent works of Esnault and Kerz [33].

Using the vanishing theorems, and ideas going back to Gabber–Loeser and Katz, we can construct tannakian categories with the convolution on G as tensor operation. Using these, and Deligne’s Riemann Hypothesis over finite fields, we obtain the following equidistribution theorem for the Fourier transforms of trace functions on G, i.e., for families of exponential sums parameterized by characters of G.

**Theorem 2 (Equidistribution on average for arithmetic Fourier transforms).** Let G be a connected commutative algebraic group over k. Let M be a geometrically simple ℓ-adic perverse sheaf on G that is pure of weight zero, with complex-valued trace functions \( t_M(x; k_n) : G(k_n) \to \mathbb{C} \) for \( n \geq 1 \). There exists an integer \( r \geq 0 \) and a compact subgroup \( K \subset U_r(\mathbb{C}) \) of the unitary group such that the sums

\[
S(M, \chi) = \sum_{x \in G(k_n)} t_M(x; k_n) \chi(x)
\]

for complex-valued characters \( \chi \) of \( G(k_n) \) become equidistributed on average in \( \mathbb{C} \) with respect to the image by the trace of the Haar probability measure \( \mu \) on K. That is, for any bounded continuous function \( f : \mathbb{C} \to \mathbb{C} \), the following equality holds:

\[
\lim_{N \to +\infty} \frac{1}{N} \sum_{1 \leq n \leq N} \frac{1}{|G(k_n)|} \sum_{\chi \in \text{char}(G(k_n))} f(S(M, \chi)) = \int_K f(\text{Tr}(x)) d\mu(x),
\]

where \( \chi \) runs over all characters of \( G(k_n) \).

The general version of this theorem appears as Theorem 4.8. Under an additional assumption (which holds for tori, abelian varieties and \( G_a \), at least), we can also deduce it from Theorem 4.11, which is a more precise equidistribution result for unitary conjugacy classes of Frobenius in the compact group K. (The difference between these two statements is quite similar to the difference between the Frobenius equidistribution theorem for cycle types of Frobenius classes in the Galois group of a polynomial, viewed as a permutation group, and the more precise Chebotarev density theorem.)

**Remark 2.** (1) In the classical setting of \( G_a \) and the Fourier transform, the group K is a maximal compact subgroup of the arithmetic monodromy group of the (lisse sheaf underlying the) \( \ell \)-adic Fourier transform of M (see Proposition 3.32).

Note that this is in contrast with more usual versions of Deligne’s equidistribution theorem, without the extra Cesàro average over \( n \), where the focus is on the geometric monodromy group (see, e.g., the versions of Katz [61, Ch.3] and Katz–Sarnak [72, Ch.9]). This slight change of emphasis extends to the general situation, and means that we can avoid additional (necessary)
assumptions such as the equality of the geometric and arithmetic monodromy groups, which occur frequently otherwise (see, e.g., [61, §3.3]), and are not always easy to check.

The Cesàro average can of course be interpreted as a form of “smoothing” (a “summation method” in the classical terminology). Although it is quite natural, it can be replaced by many others (see Remark 4.7).

(3) We will also discuss a “horizontal” version, where we consider suitable families \((M_p)\) of perverse sheaves over \(\mathbb{F}_p\) for primes \(p \to +\infty\). However, such results depend on a more quantitative version of the stratified vanishing theorem, which we have not established in full generality yet.

(4) As already mentioned, this equidistribution theorem is essentially Deligne’s equidistribution theorem on average for the \(\ell\)-adic Fourier transform of \(M\) when \(G = G_a\). When \(G\) is the multiplicative group (or its non-split form), one obtains (an average version of) Katz’s equidistribution theorem [68]. In [70], Katz proves a similar theorem for elliptic curves.

(5) The assumption that \(G\) is connected arises from the fact that the Lang torsor construction is only applicable in this case. For the purpose of equidistribution results, however, one can easily handle a non-connected algebraic group by considering one by one the restrictions to the neutral component of \(G\) of the objects \([\{x \mapsto c^{-1} x\}^* M]\), where \(c\) runs over representatives of the connected components of \(G\). (Note that different connected components might give rise to exponential sums with different distributions.)

Example 1. A simple concrete class of examples where we obtain equidistribution statements is the following (in the case when \(G\) is not an abelian variety): assume that \(k = \mathbb{F}_p\), and let \(d\) be the dimension of \(G\); then for any non-constant function \(f : G \to \mathbb{A}^1\), there exists a perverse sheaf \(M_f\) such that

\[
t_{M_f}(x; \mathbb{F}_p^n) = \frac{(-1)^d}{p^{nd/2}} e\left(\frac{\text{Tr}_{\mathbb{F}_p^n/\mathbb{F}_p}(f(x))}{p}\right)
\]

for all \(n \geq 1\) and \(x \in G(\mathbb{F}_p^n)\) (where \(e(z) = \exp(2i\pi z))\), so that Theorem 2 shows that the exponential sums

\[
\frac{1}{p^{nd/2}} \sum_{x \in G(\mathbb{F}_p^n)} \chi(x)e\left(\frac{\text{Tr}_{\mathbb{F}_p^n/\mathbb{F}_p}(f(x))}{p}\right)
\]

(which are intuitively sums over \(d\) variables) become equidistributed on average, with limiting measure of a very specific kind.

Specializing even more to \(G = G_m^d\), the function \(f\) is a Laurent polynomial in \(d\) variables \(x_1, \ldots, x_d\) and their inverses, and these exponential sums become the sums

\[
\frac{1}{p^{nd/2}} \sum_{x_1, \ldots, x_d \in \mathbb{F}_p^\times} \chi_1(x_1) \cdots \chi_d(x_d)e\left(\frac{\text{Tr}_{\mathbb{F}_p^n/\mathbb{F}_p}(f(x))}{p}\right)
\]

parameterized by a tuple \((\chi_1, \ldots, \chi_d)\) of characters of \(\mathbb{F}_p^\times\).

As a further concrete application, we will see how to deduce statements like the following, which considerably strengthens earlier work of Hall, Keating and Roddity-Gershon [52].

**Theorem 3 (Variance of the von Mangoldt function of the Legendre elliptic curve).** Let \(k\) be a finite field of characteristic \(\geq 5\). Let \(E\) be the Legendre elliptic curve with affine model

\[
y^2 = x(x - 1)(x - t)
\]
over the field $k(t)$. Let $\Lambda_{E/k(t)}$ be the von Mangoldt function of $E$, defined by the generating series

$$L(E/k(t), T) = \sum_g \Lambda_{E/k(t)}(g)T^{\deg(g)}$$

over monic polynomials $g \in k[t]$.

Let $f \in k[t]$ be a square-free polynomial of degree $\geq 4$ and set $B = k[t]/fk[t]$. Let $m \geq 1$ be an integer. For any $a \in B$, consider the sum

$$\psi_E(m; f, a) = \sum_{g \equiv a \ (\text{mod } f)} \Lambda_{E/k(t)}(g)$$

over monic polynomials of degree $m$ with coefficients in $k$. Let $a$ be the degree of the greatest common divisor of $f$ and $t(t - 1)$. Then the following equality holds:

$$\lim_{|k| \to +\infty} \frac{1}{|k|^2} \frac{1}{|B|} \sum_{a \in B} \left| \psi_E(m; f, a) - \frac{1}{|B|} \sum_{a \in B} \psi_E(m; f, a) \right|^2 = \min(m, 2\deg(f) - 2 + a).$$

This theorem is proved at the end of Chapter 11.

**Remark 3.** (1) The meaning of the limit is that we replace $k$ by its extensions $k_n$ of degree $n \geq 1$ and let $n \to +\infty$, and compute the variance for $E$ based-changed to $k_n$ (note that $B$ depends on $k$, so it is also replaced by $k_n[t]/fk_n[t]$).

(2) The version in [52] requires the assumption $\deg(f) > 900$ and moreover that the greatest common divisor of $t(t - 1)$ and $f$ is equal to $t$. We have greatly relaxed the former condition and fully removed the latter, which was recognized as being quite artificial (see [52, Rem 11.0.2]).

These improvements are due to the consideration of the problem in its natural setting, involving characters of a torus of dimension $\deg(f)$, whereas the authors of [52] used cosets of a one-dimensional torus together with Katz’s work on $G_m$.

We also give a proof of an unpublished theorem of Katz [67] answering a question of Tsimerman about equidistribution of Artin $L$-functions on curves over finite fields.

**Theorem 4 (Katz).** Let $C$ be a smooth projective geometrically connected curve of genus $g \geq 2$ over a finite field $k$ and let $D = \sum r_ix_i$ be a divisor of degree one on $C$. For each geometrically non-trivial character $\varpi$: $\pi_1(C)_{\text{ab}} \to \mathbb{C}^\times$ of finite order such that $\prod \varpi(Fr_{k(x_i), x_i})^{r_i} = 1$, we write its normalized Artin $L$-function as

$$L(\varpi, T/\sqrt{|k|}) = \det(1 - T\Theta_{C/k, \varpi})$$

for a conjugacy class $\Theta_{C/k, \varpi}$ in the unitary group $U_{2g-2}(\mathbb{C})$.

(1) If $C$ is non-hyperelliptic and $(2g - 2)D$ is a canonical divisor on $C$, then the classes $\Theta_{C/k, \varpi}$ lie in $SU_{2g-2}(\mathbb{C})$ and become equidistributed with respect to the image on the space of conjugacy classes of the Haar probability measure of $SU_{2g-2}(\mathbb{C})$.

(2) If $C$ is hyperelliptic, the hyperelliptic involution has a fixed point $O \in C(k)$ and $D = O$, then the classes $\Theta_{C/k, \varpi}$ lie in $USp_{2g-2}(\mathbb{C})$ and become equidistributed with respect to the image on the space of conjugacy classes of the Haar probability measure on $USp_{2g-2}(\mathbb{C})$.

See Chapter 12 for the proof of this result, as well as some more general statements (including, in Theorem 12.5, a result where the algebraic group $G$ occurring may involve abelian, toric and unipotent parts).
2. Outline

In this section, we present the plan of the book, and we sketch one of the main ideas of the proof of Theorem 2, in order to point out the key difficulties for groups of dimension bigger than one, which are solved using Sawin’s quantitative sheaf theory [100].

The book is organized as follows:

- In Chapter 1, we state some preliminary results; these include a survey of the formalism of quantitative sheaf theory [100], as well as basic structural results concerning commutative algebraic groups and character sheaves.

- In Chapter 2, we prove the generic and stratified vanishing theorems for commutative algebraic groups over finite fields. The very rough idea is to prove a relative version of the vanishing theorems for the various basic types of commutative groups, with a good control of the implicit constant. These relative statements are of independent interest. For example, in the case of tori, Gabber–Loeser [46] prove the stratified vanishing theorem as stated above only under the assumption that resolution of singularities over \( k \) holds for up to the dimension of the torus. We remove this assumption using alterations. For abelian varieties, we extend Weissauer’s work [113] by proving a relative version of the theorem, which involves the use of Orgogozo’s work [97] on constructibility and moderation.

- In Chapter 3, we construct a suitable tannakian category of perverse sheaves on a commutative group over a finite field with convolution as tensor operation, and establish its basic properties, as well as those of the corresponding tannakian monodromy group. We will see that some subtleties arise when defining “Frobenius conjugacy classes” corresponding to characters of \( G \).

- In Chapter 4, we combine these two ingredients to establish a number of “vertical” equidistribution theorems; there are some issues when we want to refine the statements at the level of conjugacy classes (related to those of the previous sections), which we are not currently able to solve in full generality, although we can always establish equidistribution for the characteristic polynomials.

- Chapter 2 introduces a selection of first applications of a general nature. These include the following:

  (1) the definition of the analogue of the L-function for arithmetic Fourier transforms, which is used to give information on finite tannakian groups over abelian varieties (Chapter 5);

  (2) a stratification result for exponential sums, similar to those of Katz, Laumon and Fouvy, although currently often restricted to the “vertical” direction (Chapter 6);

  (3) a generic Fourier inversion formula (Chapter 7);

  (4) some preliminary results of independence of \( \ell \) for the tannakian group when working with perverse sheaves which are part of a compatible system (Chapter 8);

  (5) various results of “Diophantine group theory”, where averages of exponential sums are related to invariants of the tannakian group; this includes in particular Larsen’s Alternative, but also some criteria to recognize the exceptional group \( E_6 \) (Chapter 9).

- Chapters 10, 11 and 12 contain applications to concrete cases. The algebraic groups involved are, respectively, the product \( G_a \times G_m \), higher-dimensional tori, and jacobians.
of curves, as well as the intermediate jacobian of a smooth cubic threefold (where the relevant Tannakian group is $E_6$, as first shown in the complex setting by Krämer).

– In Chapter 13, we list some open questions and problems. To paraphrase Katz ([68, p. 18]): “Much remains to be done”.

– Finally, we include appendices to survey the basic theory of perverse sheaves (Appendix A), to recall the most important results of Katz concerning the arithmetic Mellin transform on $G_m$ (Appendix B), and to recall the product formula of Laumon for the epsilon factor of L-functions over finite fields (Appendix C). We conclude by reproducing, with Deligne’s permission, the letter to Kazhdan in which the $\ell$-adic Fourier transform was first discussed (Appendix D), and we attempt to sketch the intuitive nature of the theory of general trace functions, to provide some intuition for analytic number theorists in Appendix E.

We now survey the key analytic step in the proof of Theorem 2 (see Proposition 4.12).

We can work with trace functions and characters with values in $\mathbb{Q}_\ell$ by using some isomorphism $\iota: \mathbb{Q}_\ell \to \mathbb{C}$, which we fix and view as an identification. The first step, following from the generic vanishing theorem, will be to prove that there exist subsets $\mathcal{Y}(k_n)$ of characters of $G(k_n)$ and conjugacy classes $\Theta_{M,k_n}(\chi)$ in some unitary group $U_r(\mathbb{C})$ such that $\text{Tr}(\Theta_{M,k_n}(\chi)) = S(M,\chi)$ for $\chi \in \mathcal{Y}(k_n)$ and $|\mathcal{Y}(k_n)| \sim |G(k_n)|$ as $n \to +\infty$. The second step (an application of the theory of tannakian categories) will be an intrinsic a priori definition of the compact group $K$ for which equidistribution should hold.

By (essentially) the Weyl criterion for equidistribution, Theorem 2 will follow from the proof that, for every non-trivial irreducible representation $\varrho$ of the unitary group $U_r(\mathbb{C})$, the limit

$$\lim_{N \to +\infty} \frac{1}{N} \sum_{1 \leq n \leq N} \frac{1}{|G(k_n)|} \sum_{\chi \in \mathcal{Y}(k_n)} \text{Tr}(\varrho(\Theta_{M,k_n}(\chi)))$$

exists and is equal to the multiplicity of the trivial representation in the restriction of $\varrho$ to the subgroup $K$.

The tannakian formalism and the Grothendieck–Lefschetz trace formula yield on the one hand the equality

$$\text{Tr} \varrho(\Theta_{M,k_n}(\chi)) = \sum_{x \in G(k_n)} \chi(x) t_{\varrho(M)}(x; k_n)$$

for $n \geq 1$ and $\chi \in \mathcal{Y}(k_n)$, and on the other hand the equality

$$\sum_{x \in G(k_n)} \chi(x) t_{\varrho(M)}(x; k_n) = \sum_{|j| \leq d} (-1)^j \text{Tr}(\text{Fr}_{k_n} | H^j_c(G_k, \varrho(M) \otimes L_\chi))$$

for $n \geq 1$ and any character $\chi$ of $G(k_n)$, where $\text{Fr}_{k_n}$ is the geometric Frobenius automorphism of $k_n$.

The definition of the set $\mathcal{Y}(k_n)$ implies in particular the property that for $\chi \in \mathcal{Y}(k_n)$, the only possibly non-zero term in the right-hand side of (2) is the one with $j = 0$. Thus we have

$$\sum_{\chi \in \mathcal{Y}(k_n)} \text{Tr} \varrho(\Theta_{M,k_n}(\chi)) = \sum_{\chi \in \mathcal{Y}(k_n)} \text{Tr}(\text{Fr}_{k_n} | H^0_c(G_k, \varrho(M) \otimes L_\chi)).$$
If we add to the right-hand side of this last expression the two sums
\[ S_1 = \sum_{\chi \notin \mathcal{Y}(k_n)} \text{Tr}(\text{Fr}_{k_n} | H^0_c(G_k, \mathcal{O}(M) \otimes \mathcal{L}_\chi)), \]
\[ S_2 = \sum_{1 \leq |j| \leq d} \sum_{\chi \notin \mathcal{Y}(k_n)} (-1)^j \text{Tr}(\text{Fr}_{k_n} | H^j_c(G_k, \mathcal{O}(M) \otimes \mathcal{L}_\chi)), \]
then the resulting quantity is
\[ \sum_{|j| \leq d} \sum_{\chi \notin \mathcal{G}(k_n)} (-1)^j \text{Tr}(\text{Fr}_{k_n} | H^j_c(G_k, \mathcal{O}(M) \otimes \mathcal{L}_\chi)) = \sum_{\chi \in \mathcal{G}(k_n)} \sum_{x \in \mathcal{G}(k_n)} \chi(x) t_{\mathcal{O}(M)}(x; k_n) = \sum_{x \in \mathcal{G}(k_n)} t_{\mathcal{O}(M)}(x; k_n) \sum_{\chi \in \mathcal{G}(k_n)} \chi(x) = |\mathcal{G}(k_n)| t_{\mathcal{O}(M)}(1; k_n) \]
by the trace formula again, followed by an exchange of the sums and an application of the orthogonality of characters of finite abelian groups. This is a single value of the trace function, and it is relatively straightforward to show that it gives the desired multiplicity as limit. So the key difficulty is to control the two auxiliary sums $S_1$ and $S_2$.

This can be done if:

1. We have some bound on the size of the individual traces $\text{Tr}(\text{Fr}_{k_n} | H^j_c(G_k, \mathcal{O}(M) \otimes \mathcal{L}_\chi))$;
2. We have some bound on the number of $\chi$ where $H^j_c$ can be non-zero for a given $j$.

The second bound is given by the stratified vanishing theorem for $\mathcal{O}(M)$. For the first, Deligne's Riemann Hypothesis (see Theorem A.19) implies the inequality
\[ |\text{Tr}(\text{Fr}_{k_n} | H^j_c(G_k, \mathcal{O}(M) \otimes \mathcal{L}_\chi))| \leq |k_n|^{(j-d)/2} \dim H^j_c(G_k, \mathcal{O}(M) \otimes \mathcal{L}_\chi), \]
and we see that we require a bound on the dimension of the cohomology spaces, which should be independent of $\chi$. We obtain such bounds as special cases of Sawin’s quantitative sheaf theory [100], which is a quantitative form of the finiteness theorems for the six operations on the derived category of $\ell$-adic sheaves on quasi-projective algebraic varieties.

**Remark 4.** If $G$ is one-dimensional, then the Euler–Poincaré characteristic formula (see Theorem C.2) easily implies precise bounds on the dimension of the cohomology spaces that arise, and hence this critical issue does not arise for the additive or multiplicative groups, or for elliptic curves (for such groups, Theorem 1 is also straightforward). It also does not arise if the set $\mathcal{Y}(k_n)$ is the whole group $\mathcal{G}(k_n)$, which is the case in some instances considered by Katz for higher-dimensional abelian varieties.

### 3. Conventions and notation

We summarize the notation that we use, as well as some typographical conventions that we follow consistently unless otherwise specified.

Given complex-valued functions $f$ and $g$ defined on a set $S$, we write $f \ll g$ if there exists a real number $C \geq 0$ (called an “implicit constant”) such that the inequality $|f(s)| \leq C g(s)$ holds for all $s \in S$. We write $f \asymp g$ if $f \ll g$ and $g \ll f$. If $f$ and $g$ are defined on a topological space $X$, and $\mathcal{F}$ is a filter on $X$, then we say that $f \sim g$ along $\mathcal{F}$ if $\lim_{\mathcal{F}} f(x)/g(x) = 1$.

For any complex number $z$, we write $e(z) = \exp(2i\pi z)$; for $q \geq 1$ and $a \in \mathbb{Z}/q\mathbb{Z}$, the value $e(a/q)$ is then well-defined.
By a variety over a field $k$, we mean a reduced separated $k$-scheme of finite type. In particular, an algebraic group, as opposed to a group scheme, is always supposed to be reduced, and hence smooth if the field $k$ is perfect.

Let $S$ be a scheme. We say that a pair $(X, u)$ is a quasi-projective scheme over $S$ if $X$ is a scheme over $S$ and $u$ is a locally-closed immersion $u : X \to \mathbf{P}^n_S$ for some integer $n \geq 0$. We call $n$ the embedding dimension of $(X, u)$, or simply of $u$, and we say that $u$ is a quasi-projective embedding of $X$. If $S$ is the spectrum of a field $k$ and $X$ is a variety over $k$, we will speak of quasi-projective varieties over $k$. In some cases, we omit the mention of $u$, when it is clear in context which locally-closed immersion is used. By a morphism $f : (X, u) \to (Y, v)$ of quasi-projective schemes over $S$, we mean an $S$-morphism of the underlying schemes.

An algebraic group $G$ over an algebraically closed field of characteristic zero is called reductive if all its finite-dimensional representations are completely reducible (that is, we do not require $G$ to be connected).

Let $X$ be a scheme and $\ell$ a prime number invertible on $X$. Perverse sheaves (when $X$ is an algebraic variety defined over a field $k$) are always considered with respect to the middle perversity. We include a short survey of the most important properties of perverse sheaves in Appendix A, but recall here some of the definitions. An $\ell$-adic complex is said to be semiperverse if, for any integer $i$, the support of the cohomology sheaf $\mathcal{H}^i(M)$ is of dimension at most $-i$. This is equivalent to the fact that the perverse cohomology sheaves $\mathcal{H}^i(M)$ are zero for $i \geq 1$ (see [6, Prop. 1.3.7]).

We say that a complex $M$ in $D^b_c(X, \mathcal{O}_\mathbf{Q}_\ell)$ has perverse amplitude $[a, b]$ if its perverse cohomology sheaves $\mathcal{H}^i(M)$ are zero for $i \notin [a, b]$.

A stratification $\mathcal{X}$ of $X$ is a finite set-theoretic partition of the associated reduced scheme $X^{\text{red}}$ into non-empty reduced locally-closed subschemes of $X$, called the strats of $\mathcal{X}$.

Let $\mathcal{X}$ be a stratification of $X$, and let $F$ be an $\ell$-adic sheaf on $X$. The sheaf $F$ is said to be tame and constructible along $\mathcal{X}$ if it is tamely ramified, in the sense explained in [97, §1.3.1], and if its restriction to any strat of $\mathcal{X}$ is a lisse sheaf. More generally, a complex $M \in D^b_c(X, \mathcal{O}_\mathbf{Q}_\ell)$ is said to be tame and constructible along $\mathcal{X}$ if all its cohomology sheaves are tame and constructible along $\mathcal{X}$.

Let $f : X \to Y$ be a morphism of schemes. For an object $M$ of $D^b_c(X, \mathcal{O}_\mathbf{Q}_\ell)$, we write $Rf_!M = Rf_*M$ to indicate that the canonical “forget support” morphism $Rf_!M \to Rf_*M$ is an isomorphism (and similarly for equality of cohomology groups with and without compact support).

Let $q \geq 1$ and $w \in \mathbb{Z}$ be integers. A complex number $\alpha$ is called a $q$-Weil number of weight $w$ if $\alpha$ is algebraic over $\mathbb{Q}$ and all its Galois conjugates have modulus $q^{w/2}$. If $k$ is a finite field, then a $k$-Weil number is a $|k|$-Weil number.

Throughout, for any prime $\ell$, we consider a fixed isomorphism $\iota_0 : \mathbf{Q}_\ell \to \mathbf{C}$. Trace functions of $\ell$-adic perverse sheaves are thus always identified with complex-valued functions through $\iota_0$, and $\ell$-adic characters are identified with complex characters. On the other hand, purity of perverse sheaves (or lisse sheaves or $\ell$-adic complexes) refers to purity in the sense of Deligne, i.e., pointwise purity means that the eigenvalues of Frobenius are Weil numbers of some weight; see the survey in Section A.3.

The following notation are used consistently in all the book, although frequently with reminders (some objects, such as character sheaves, will be defined later).

$- X - Y$: difference set (elements of $X$ that are not in $Y$); also used in scheme-theoretic settings.
- \(|X|\): cardinality of a set \(X\).
- \(D^b_c(X) = D^b_c(X, \overline{Q}_{\ell})\): category of bounded constructible complexes of \(
\overline{Q}_{\ell}\)-sheaves on a scheme \(X\) such that the prime \(\ell\) is invertible in \(X\).
- \(K(X) = K(X, \overline{Q}_{\ell})\): the Grothendieck group (or ring) of \(D^b_c(X)\); it has a basis consisting of classes of simple perverse sheaves (see [87, §0.8]).
- \(\alpha_{\deg}\): for \(k\) a finite field and \(\alpha\) an \(\ell\)-adic unit, the \(\ell\)-adic sheaf of rank 1 on \(\text{Spec}(k)\) on which the geometric Frobenius acts by multiplication by \(\alpha\); more generally, for \(f: X \to \text{Spec}(k)\) a scheme over \(k\), the pullback to \(X\) of \(\alpha_{\deg}\).
- \(M \otimes N\): derived tensor product of objects of \(D^b_c(X)\).
- \(\text{Perv}(X) = \text{Perv}(X, \overline{Q}_{\ell})\): the category of \(\ell\)-adic perverse sheaves on \(X\). A simple perverse sheaf will also sometimes be called an irreducible perverse sheaf.
- \(\text{D}(M)\): the Verdier dual of a complex \(M\).
- \(\mathcal{H}^i(M)\): for \(M \in D^b_c(X)\), the \(i\)-th cohomology sheaf of \(M\).
- \(\mathcal{H}^i_c(M)\): \(\text{étale}\) cohomology groups with compact support.
- \(h^i(X_{\overline{k}}, M) = \dim H^i(X_{\overline{k}}, M)\).
- \(\chi(X_{\overline{k}}, M), \chi_c(X_{\overline{k}}, M)\): Euler–Poincaré characteristic for cohomology or cohomology with compact support.
- \(t_M(x; k_n)\): Frobenius trace function of an object \(M\) of \(D^b_c(X)\) for \(x \in X(k_n)\); \(t_M(x) = t_M(x; k)\).
- \(\langle M \rangle\)
- \(G^\text{arith}_M \text{ (resp. } G^\text{geo}_M\): arithmetic (resp. geometric) tannakian group associated with a perverse sheaf \(M\).
- \(\tilde{G}(k_n)\): group of \(\overline{Q}_{\ell}\)-characters of the finite group \(G(k_n)\).
- \(\hat{G}\): disjoint union of the sets \(\tilde{G}(k_n)\) for \(n \geq 1\).
- \(\Pi(G)\): for a semiabelian variety \(G\), the \(\overline{Q}_{\ell}\)-scheme of \(\ell\)-adic characters of \(G\).
- \(\mathcal{L}_\chi\): character sheaf on \(G_{k_n}\) associated to a character \(\chi \in \tilde{G}(k_n)\).
- \(M_\chi\): for an object \(M\) of \(D^b_c(G)\) and a character \(\chi\), the object \(M \otimes \mathcal{L}_\chi\).

Moreover, the following notational conventions will be used (often with reminders).

- \(k\): a finite field of characteristic \(p\).
- \(\ell\): a prime different from \(p\).
- \(\overline{k}\): an algebraic closure of \(k\).
- \(k_n\): the extension of degree \(n\) of \(k\) inside \(\overline{k}\).
– G: a connected commutative algebraic group (in particular of finite type) defined over $k$.
– T: a torus; U: a unipotent group; A: an abelian variety.
– $\mathcal{F}$: a $\overline{Q}_r$-sheaf; $\mathcal{L}$: a $\overline{Q}_r$-lisse sheaf of rank one.
– M, N: objects of $D^b_c(X)$ or $\text{Perv}(X)$. 
Part 1

Theoretical foundations
In this chapter, we summarize some tools we use throughout the book, especially the basic properties of Sawin’s quantitative sheaf theory \[100\] with an emphasis on commutative algebraic groups.

### 1.1. Review of quantitative sheaf theory

Let \(k\) be a field, \(\bar{k}\) an algebraic closure of \(k\), and \(\ell\) a prime number different from the characteristic of \(k\).

**Definition 1.1 (Complexity).**

1. Assume \(k = \bar{k}\) is algebraically closed. Let \(M^{n+1,m+1}\) be the variety of \((n+1) \times (m+1)\) matrices of maximal rank, viewed as an affine scheme over \(k\). For each \(0 \leq m \leq n\), consider a geometric generic point \(a_m\) of \(M^{n+1,m+1}\) defined over an algebraically closed extension \(K\) of \(k\), and let \(l_{a_m} : \mathbb{P}_K^{n} \rightarrow \mathbb{P}_K^{m}\) denote the associated linear map.

(a) The complexity of an object \(M\) of \(D^b_{\text{c}}(\mathbb{P}_k^n)\) is defined as
\[
c(M) = \max_{0 \leq m \leq n} \sum_{i \in \mathbb{Z}} h^i(\mathbb{P}_K^n, M \otimes l_{a_m}^* \mathbb{Q}_\ell) = \max_{0 \leq m \leq n} \sum_{i \in \mathbb{Z}} h^i(\mathbb{P}_K^m, l_{a_m}^* M),
\]
where the last equality follows from the projection formula.

(b) Let \((X, u)\) be a quasi-projective variety over \(k\). For any object \(M\) of \(D^b_{\text{c}}(X)\), the complexity of \(M\) with respect to \(u\) is defined as \(c_u(M) = c(u^! M)\).

2. Let \(k\) be a field. Let \((X, u)\) be a quasi-projective variety over \(k\) and \(M\) an object of \(D^b_{\text{c}}(X)\). We define \(c_u(M) = c_{\bar{k}}(M_{\bar{k}})\), the complexity of the base change of \(M\) to \(X_{\bar{k}}\).

The invariance of étale cohomology under base change between algebraically closed fields implies that the complexity is well-defined (i.e., it does not depend on the choice of field of definition of the generic points \(a_m\)).

**Lemma 1.2.** Let \((X, u)\) be a quasi-projective variety over \(k\) and let \(M\) be an object of \(D^b_{\text{c}}(X)\). The following inequality holds:
\[
\sum_{i \in \mathbb{Z}} h^i_c(X_{\bar{k}}, M) \leq c_u(M).
\]

**Proof.** This follows from the equality \(h^i_c(X_{\bar{k}}, M) = h^i(\mathbb{P}_K^n, u^! M)\) and the invariance of étale cohomology under extension of scalars between algebraically closed fields, combined with the fact that \(l_{a_m} : \mathbb{P}_K^n \rightarrow \mathbb{P}_K^m\) is an isomorphism. \(\square\)

The following simple fact will be useful.

**Proposition 1.3.** Let \(f : (X, u) \rightarrow (Y, v)\) be a finite surjective radicial morphism of quasi-projective varieties over \(k\). For each object \(M\) of \(D^b_{\text{c}}(Y)\), the equality \(c_{u \circ f}(f^* M) = c_u(M)\) holds.
PROOF. Let $n$ be the embedding dimension of $u$. Using the notation of Definition 1.1, for each $0 \leq m \leq n$ and each $i \in \mathbb{Z}$, there is a canonical isomorphism
\[ H^i(P^u_{K,i}(u \circ f)) f^*M \otimes l_{a,m} \cong H^i(P^u_{K,i} u M \otimes l_{a,m} \overline{Q}_i) \]
since, for $f$ finite surjective radical, the adjunction map $M \to f_* f^* M = f_! f^* M$ is an isomorphism (see, e.g. [43, Cor. 5.3.10]), hence the result.

DEFINITION 1.4. Let \( f : (X, u) \to (Y, v) \) be a morphism of quasi-projective varieties over $k$ with embedding dimensions $n_X$ and $n_Y$ respectively. For all integers \( 0 \leq m_X \leq n_X \) and \( 0 \leq m_Y \leq n_Y \), consider geometric generic points \( a_X \) of \( M_{m_X+1,n_X+1} \) and \( b_Y \) of \( M_{m_Y+1,n_Y+1} \) defined over an algebraically closed extension $K$ of $k$, and let \( l_{a_X} : P^u_{m_X} \to P^u_{K} \) and \( l_{b_Y} : P^v_{m_Y} \to P^v_{K} \) denote the associated linear maps. The complexity of $f$ is defined as
\[
c_{u,v}(f) = \max_{0 \leq m_X \leq n_X} \max_{0 \leq m_Y \leq n_Y} \sum_{i \in \mathbb{Z}} b_i(X, u^* l_{a_X}, \overline{Q}_i) \otimes f^* v^* l_{b_Y}.
\]

The main result of [100] establishes, among other things, the “continuity” of the six operations on the derived category with respect to the complexity. In this result and the remainder of this section, the implicit constants depend only on the embedding dimensions of the quasi-projective varieties, unless otherwise specified.

THEOREM 1.5 ([100, Th. 6.8 and Prop. 6.14]). Let \( f : (X, u) \to (Y, v) \) be a morphism of quasi-projective varieties over $k$. Let $M, N, P$ be objects of $D^b_c(X)$ and let $Q$ be an object of $D^b_c(Y)$. The following holds inequalities hold:

1. \( c_u(M \oplus N) = c_u(M) + c_u(N) \).
2. \( c_u(M \otimes N) \leq c_u(M)c_u(N) \).
3. if $M \to N \to P$ is a distinguished triangle, then \( c_u(N) \leq c_u(M) + c_u(P) \).
4. \( c_u(M[k]) = c_u(M) \) for any $k \in \mathbb{Z}$.
5. \( c_u(R\text{Hom}(M, N)) \leq c_u(\text{id}(u)c_u(M)c_u(N)) \).
6. \( c_u(Rf_! M) \leq c_{u,v}(f)c_u(M) \) and \( c_v(Rf_* M) \leq c_{u,v}(\text{id}(u)c_v(v)c_{u,v}(f)c_u(M)) \).
7. \( c_u(f^* Q) \leq c_{u,v}(f)c_v(Q) \) and \( c_v(f^! Q) \leq c_{u,v}(\text{id}(u)c_v(v)c_{u,v}(f)c_v(Q)) \).

In all these estimates the implied constants depend only on the embedding dimensions of $u$ and $v$.

REMARK 1.6. Although the notion of complexity on a quasi-projective scheme $(X, u)$ depends on the quasi-projective immersion $u$, note that if $v$ is another quasi-projective immersion of $X$, then applying the property (7) to the identity morphism between $(X, u)$ and $(X, v)$, we get
\[
c_{u}(M) \asymp c_{v}(M)
\]
for all objects $M$ of $D^b_c(X)$, where the implied constants are essentially $c_{u,v}(\text{id})$ and $c_{v,u}(\text{id})$, up to constants depending on the embedding dimensions of $u$ and $v$. Thus, as long as we only consider on $X$ an absolutely bounded number of different quasi-projective immersions, we can think of the complexity as being essentially independent of them. (This is reminiscent of similar properties of height functions in diophantine geometry.)

The complexity can also be used to control the degree of the locus where a complex of sheaves is lisse, and of the locus where the generic base change theorem holds.

THEOREM 1.7 ([100, Th. 6.22]). Let $(X, u)$ be an irreducible quasi-projective variety over $k$. Let $M$ be an object of $D^b_c(X)$. Let $Z$ be the complement of the maximal open subset where $X$ is smooth and $M$ is lisse. Then the estimate
\[
\deg(u(Z)) \ll (3 + s)c(u)c_u(M)
\]
holds, where the degrees are computed in the projective space target of $u$, and $s$ is the degree of the codimension $1$ part of the singular locus of $X$.

**Theorem 1.8 ([100, Th. 6.26]).** Let $(X, u)$, $(Y, v)$ and $(S, w)$ be quasi-projective algebraic varieties over $k$. Let $f : X \rightarrow Y$ and $g : Y \rightarrow S$ be morphisms.

For any object $M$ of $D^b_c(X)$, there exists an integer $C \geq 0$, depending only on $c_u(M)$ and $(f, g, u, v, w)$, and a dense open set $U \subset S$ such that

(i) The image of the complement of $U$ has degree $\leq C$.

(ii) The object $f_*M$ is of formation compatible with any base change $S' \rightarrow U \subset S$.

**Proposition 1.9 ([100, Th. 6.15]).** Let $(X, u)$ be a quasi-projective variety over $k$. Let $M$ be an object of $D^b_c(X)$. For each integer $i$, let $M_{i,1}, \ldots, M_{i,n_i}$ denote the Jordan-Hölder factors of the perverse cohomology sheaf $\mathcal{H}^i(M)$. Then the following estimate holds:

$$
\sum_{i \in \mathbb{Z}} \sum_{1 \leq j \leq n_i} c_u(M_{i,j}) \ll c_u(id(u))c_u(M).
$$

We also recall the quantitative statement of the Riemann Hypothesis when interpreted as a quasi-orthogonality statement.

**Theorem 1.10 ([100, Th. 7.13 (2)]).** Let $k$ be a finite field and $\ell$ a prime different from the characteristic of $k$. Let $(X, u)$ be a quasi-projective algebraic variety over $k$. Let $M$ and $N$ be geometrically simple $\ell$-adic perverse sheaves on $X$ that are pure of weight zero, with complex trace functions $t_M$ and $t_N$ respectively. Then the estimate

$$
\sum_{x \in X(k)} |t_M(x)\overline{t_N(x)}| \ll c_u(M)c_u(N)|k|^{-1/2}
$$

holds if $M$ and $N$ are not geometrically isomorphic, whereas

$$
\sum_{x \in X(k)} |t_M(x)|^2 = 1 + O(c_u(M)^2|k|^{-1/2}).
$$

In both estimates, the implied constants only depend on the embedding dimension of $X$ and are effective.

Finally, we have pointwise bounds for the trace functions.

**Proposition 1.11 ([100, Prop. 7.11 (2)]).** Let $k$ be a finite field and $\ell$ a prime different from the characteristic of $k$. Let $(X, u)$ be a quasi-projective algebraic variety over $k$, and let $M$ be a non-punctual simple perverse sheaf on $X$ which is pure of weight $0$. For any $n \geq 1$ and $x \in X(k_n)$, we have

$$
t_M(x; k_n) \ll \frac{1}{|k_n|^{1/2}}.
$$

**1.2. Existence of rational points**

The following lemma is standard, but we sketch the proof for completeness.

**Lemma 1.12.** Let $(X, u)$ be a non-empty quasi-projective variety over a finite field $k$ with embedding dimension $n$. There exists a finite extension $k'$ of $k$ with degree bounded in terms of $(\dim(X), \deg(u(X)), n)$ such that $X(k')$ is non-empty.

**Proof.** This follows from the Lang–Weil bound or the Riemann Hypothesis for $X$ combined with estimates for sums of Betti numbers as in [64].
1.3. Structure of commutative algebraic groups

Let \( k \) be a field and let \( G \) be a commutative algebraic group over \( k \). The scheme \( G \) is quasi-projective (see, e.g., [21, Prop. A.3.5] or [109, Lemma 39.8.7]). We will always assume that \( G \) is given with a quasi-projective immersion \( u \) of \( G \), and the complexity of \( \ell \)-adic complexes will be understood with respect to \( u \) (so that we sometimes write just \( c(M) \) instead of \( c_u(M) \)). If \( G \) is either a power of \( G_a \) or of \( G_m \), we assume that \( u \) is simply the obvious embedding in the projective space of the same dimension. We will on occasion make use of Remark 1.6 and use auxiliary quasi-projective immersions.

Smooth connected commutative algebraic groups over a finite field admit a dévissage in terms of the fundamental classes of abelian varieties, tori, unipotent\(^1\) and finite commutative group schemes. The most convenient version for us is the following statement, which follows from results of Barsotti–Chevalley and Rosenlicht (see for instance the account in the book of Brion, Samuel and Umea, combining [16, Cor. 5.5.2] with the structure theorem for connected affine commutative algebraic groups over perfect fields as a product of a unipotent group and a torus, see e.g. [15, Th. 5.3.1, (2)]).

**Proposition 1.13.** Let \( k \) be a finite field and let \( G \) be a connected commutative algebraic group over \( k \). There exist an abelian variety \( A \), a torus \( T \), a unipotent group \( U \) and a finite commutative subgroup scheme \( N \) of \( A \times U \times T \), all defined over \( k \), such that \( G \) is isomorphic to \((A \times U \times T)/N\).

We further recall that a finite commutative group scheme \( N \) over a perfect field has a unique direct product decomposition \( N = N_r \times N_l \) where \( N_r \) is reduced and \( N_l \) is local (i.e., equal to its connected component of the identity; see, e.g., [15, Prop. 2.5.4]).

1.4. Convolution

Let \( G \) be a commutative algebraic group over a field \( k \). We denote by

\[
m: G \times G \to G, \quad \text{inv}: G \to G, \quad e \in G(k)
\]

the group law, the inversion morphism, and the neutral element respectively.

**Definition 1.14 (Convolution).** The convolution product and the convolution product with compact support on \( G \) are the functors from \( \mathbb{D}^b_c(G) \times \mathbb{D}^b_c(G) \) to \( \mathbb{D}^b_c(G) \) defined as

\[
M \ast_s N = Rm_!(M \boxtimes N), \quad M \ast ! N = Rm_!(M \boxtimes N)
\]

for objects \( M \) and \( N \) of \( \mathbb{D}^b_c(G) \).

If \( G \) is projective, then so is the morphism \( m \), and hence the two convolutions agree. In general, there is a canonical “forget supports” morphism

\[
M \ast ! N \longrightarrow M \ast_s N.
\]

We will write \( M \ast ! N = M \ast_s N \) when this morphism is an isomorphism.

If \( u \) is a quasi-projective immersion of \( G \), then we deduce from Theorem 1.5 that for any objects \( M \) and \( N \), the following estimates hold:

\[
c_u(M \ast_s N) \ll c_u(M)c_u(N), \quad c_u(M \ast ! N) \ll c_u(M)c_u(N).
\]

For an object \( M \) of \( \mathbb{D}^b_c(G) \), we define

\[
M^\vee = \text{inv}^* D(M),
\]

\(^1\) In this book, “unipotent” only applies to commutative groups.
where $D(M)$ is the Verdier dual. Since $\text{inv}^* = \text{inv}^!$ commutes with $D$, the functor $M \mapsto M^\vee$ is an involution, in the sense that the functor $M \mapsto (M^\vee)^\vee$ is canonically isomorphic to the identity functor.

We denote by $1$ the skyscraper sheaf supported at the neutral element $e$ of $G$. The following lemma is analogous to [81, Lem. 3.1] and has the same proof.

**Lemma 1.15.** Let $M$ and $N$ be objects of $\text{Perv}(G)$. There exist canonical isomorphisms

<table>
<thead>
<tr>
<th>Equation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1.2)</td>
<td>$\text{Hom}(1, M^\vee <em>_</em> N) \simeq \text{Hom}(M, N) \simeq \text{Hom}(M \ast_1 N^\vee, 1)$</td>
</tr>
<tr>
<td>(1.3)</td>
<td>$D(M <em>_</em> N) \simeq D(M) \ast_1 D(N)$, $D(M \ast_1 N) \simeq D(M) <em>_</em> D(N)$</td>
</tr>
<tr>
<td>(1.4)</td>
<td>$H^<em><em>c(G</em>\mathbb{Q}, M) \otimes_{\mathbb{Q}_\mathbb{Q}} H^</em><em>c(G</em>\mathbb{Q}, N) \simeq H^*<em>c(G</em>\mathbb{Q}, M <em>_</em> N)$</td>
</tr>
<tr>
<td>(1.5)</td>
<td>$H^<em>(G_\mathbb{Q}, M) \otimes_{\mathbb{Q}} H^</em>(G_\mathbb{Q}, N) \simeq H^*(G_\mathbb{Q}, M <em>_</em> N)$.</td>
</tr>
</tbody>
</table>

In the first isomorphisms, the hom-spaces are taken in $\text{Perv}(G)$.

### 1.5. Character groups

In this section, we denote by $k$ a finite field, by $\overline{k}$ an algebraic closure of $k$, and by $k_n$ the extension of degree $n$ of $k$ in $\overline{k}$. Let $\ell$ be a prime number distinct from the characteristic of $k$.

Let $G$ be a connected commutative algebraic group defined over $k$. For each $n \geq 1$, the **norm map** is the group homomorphism $N_{k_n/k} : G(k_n) \to G(k)$ defined as $N_{k_n/k}(x) = \prod_{i=0}^{n-1} x^{[k]}$.

For any $n \geq 1$, let $\widehat{G}(k_n)$ be the group of characters $\chi : G(k_n) \to \mathbb{Q}_\ell^\times$. We denote by $\widehat{G}$ the disjoint union

$$\widehat{G} = \bigcup_{n \geq 1} \widehat{G}(k_n)$$

(note that this is not a group; we also omit the dependency on $\ell$ in this notation).

Given any set $S \subset \widehat{G}$, we also define $S(k_n) = S \cap \widehat{G}(k_n)$, so that $S$ is the disjoint union of the subsets $S(k_n)$.

Since $G$ is geometrically irreducible (see e.g. [94, Cor. 1.35]), the estimate

$$|\widehat{G}(k_n)| = |G(k_n)| = |k|^{n \dim(G)} + O(|k|^{(n-1/2) \dim(G)})$$

holds for $n \geq 1$ by the Lang–Weil estimates. If $G$ is an abelian variety we have more precisely

$$(|k|^{1/2} - 1)^{2n \dim(G)} \leq |\widehat{G}(k_n)| \leq (|k|^{1/2} + 1)^{2n \dim(G)}$$

and if $G$ is a torus, then

$$(|k| - 1)^{n \dim(G)} \leq |\widehat{G}(k_n)| \leq (|k| + 1)^{n \dim(G)}.$$ 

These can be derived from the computation of étale cohomology of abelian varieties combined with the trace formula, or from Steinberg's formula for tori; see for instance [93, Th. 15.1, Th. 19.1] for the case of abelian varieties and [18, Prop. 3.3.5] for the case of tori.

We now recall from [26, Sommes trig., 1.14] the **lang torsor construction** and the basic properties of the associated character sheaves. There is an exact sequence of commutative algebraic groups

$$1 \to G(k) \to G \xrightarrow{\Phi} G \to 1,$$

\[\text{Note that it is here that the assumption that } G \text{ is connected plays a role, since in general the image of the morphism } x \mapsto \text{Fr}_k(x) \cdot x^{-1} \text{ is contained in the connected component of the neutral element.}\]
where $\mathcal{L}$ is the Lang isogeny $x \mapsto \text{Fr}_k(x) \cdot x^{-1}$. The Lang isogeny is an étale covering, and hence induces a surjective map $\pi_1^\text{ét}(G, e) \to G(k)$. Given a character $\chi \in \widehat{G}(k)$, we denote by $\mathcal{L}_\chi$ the $\ell$-adic lisse sheaf of rank one on $G$ obtained by composing this map with $\chi^{-1}$ and we say that $\mathcal{L}_\chi$ is the character sheaf on $G$ associated to $\chi$.

For $x \in G(k)$, the geometric Frobenius automorphism at $x$ acts on the stalk of $\mathcal{L}_\chi$ at $x$ by multiplication by $\chi(x)$. In particular, the lisse sheaf $\mathcal{L}_\chi$ is pure of weight zero.

The dual $D(\mathcal{L}_\chi)$ of a character sheaf is isomorphic to $\mathcal{L}_{\chi^{-1}}$, and there are canonical isomorphisms

$$\mathcal{L}_{\chi_1} \otimes \mathcal{L}_{\chi_2} \simeq \mathcal{L}_{\chi_1 \chi_2}$$

for any two characters $\chi_1$ and $\chi_2$.

If $n \geq 1$ and $\chi \in \widehat{G}(k_n)$ is non-trivial, then for all $i \in \mathbb{Z}$, the cohomology space $H^i_c(G_\bar{k}, \mathcal{L}_\chi)$ vanishes (see [26, Sommes trig., Th. 2.7*]). More generally, we have the following relative version.

**Lemma 1.16.** Let $f : G \to H$ be a surjective morphism of commutative algebraic groups over $k$. Let $\chi \in \widehat{G}(k)$. The complex $Rf_! \mathcal{L}_\chi$ vanishes unless $\mathcal{L}_\chi | \ker(f)^\circ$ is the constant sheaf, i.e., unless $\chi$ is trivial on $\ker(f)^\circ$.

**Proof.** Let $M = Rf_! \mathcal{L}_\chi$. Let $y \in H$ and let $z \in G$ be such that $f(z) = y$. By the proper base change theorem, the stalk of $M$ at $y$ is given by

$$M_y = H^*_c(f^{-1}(y)_\bar{k}, \mathcal{L}_\chi) = H^*_c((z + \ker(f))_\bar{k}, \mathcal{L}_\chi) = H^*_c(\ker(f)_\bar{k}, [x \mapsto xz]^* \mathcal{L}_\chi | \ker(f)).$$

We write $\ker(f)$ as the disjoint union of cosets $u \ker(f)^\circ$ where $u$ runs over a set of representatives of the group of connected components of $\ker(f)$. Thus

$$H^*_c(\ker(f)_\bar{k}, [x \mapsto xz]^* \mathcal{L}_\chi | \ker(f)) = \bigoplus_u H^*_c(\ker(f)^\circ_\bar{k}, [x \mapsto xuz]^* \mathcal{L}_\chi | \ker(f)^\circ).$$

Since $\mathcal{L}_\chi$ is a character sheaf, the sheaf $[x \mapsto xuz]^* \mathcal{L}_\chi$ is geometrically isomorphic to $\mathcal{L}_\chi$, so that we have an isomorphism

$$M_y \simeq \bigoplus_u H^*_c(\ker(f)^\circ_\bar{k}, \mathcal{L}_\chi | \ker(f)^\circ),$$

and the result now follows from [26, Sommes trig., Th. 2.7*].

Let $n \geq 1$ and $\chi \in \widehat{G}(k)$. The base change of $\mathcal{L}_\chi$ to $G_{k_n}$ is the character sheaf on $G_{k_n}$ associated to the character $\chi \circ N_{k_n/k}$ of $G(k_n)$. In particular, the trace function of $\mathcal{L}_\chi$ on $k_n$ is given by

$$t_{\mathcal{L}_\chi}(x; k_n) = \chi(N_{k_n/k}(x))$$

for $x \in G(k_n)$.

When there is no risk of confusion, we will still denote by $\mathcal{L}_\chi$ the pullback of the character sheaf associated to $\chi$ to $\bar{k}$. The previous remark shows that $\chi$ and $\chi \circ N_{k_n/k}$ give rise to the same base change to $\bar{k}$.

Let $f : G \to H$ be a homomorphism of commutative algebraic groups defined over $k$. For any $n \geq 1$, denote by $f_n$ the induced morphism $G(k_n) \to H(k_n)$; then we have dual homomorphisms $\widehat{f}_n : \widehat{H}(k_n) \to \widehat{G}(k_n)$ defined by $\chi \mapsto \chi \circ f_n$. The combination of all these maps gives a map $\widehat{f} : \widehat{H} \to \widehat{G}$, which we will often denote simply by $\chi \mapsto \chi \circ f$. We will sometimes say that a character $\chi \in \widehat{G}$ arises from $H$ if $\chi$ belongs to the image of $\widehat{f}$.

For $\chi \in \widehat{H}(k_n)$, there is a canonical isomorphism $\mathcal{L}_{\widehat{f}(\chi)} \simeq f^* \mathcal{L}_\chi$. 

For any object $M$ of $D_c^b(G)$ and any character $\chi$ of $G(k)$, we denote by

$$ M_\chi = M \otimes \mathcal{L}_\chi $$

the “twist” of $M$ by the character sheaf $\mathcal{L}_\chi$.

For all $\chi \in \hat{G}$, and all objects $M$ and $N$ of $D_c^b(G)$ (or $D_c^b(G_{\bar{k}})$), there are canonical isomorphisms

(1.6) $D(M_\chi) \simeq D(M)_{\chi^{-1}}$,

(1.7) $(M_\chi)^{\vee} \simeq (M^{\vee})_\chi$,

(1.8) $(M \ast^* N)_\chi \simeq (M_\chi \ast^* N_\chi)$, $(M \ast^! N)_\chi \simeq (M_\chi \ast^! N_\chi)$.

More generally, for any algebraic variety $X$ over $k$, any morphism $f : X \to G$, and any object $M$ of $D_c^b(X)$, we denote

$$ M_\chi = M \otimes f^* \mathcal{L}_\chi, $$

and we use the same notation for objects in $D_c^b(G_{\bar{k}})$ and $D_c^b(X_{\bar{k}})$, or in $D_c^b(G_{k_n})$ and $D_c^b(X_{k_n})$.

We will extensively (and often without comment) use the following standard lemma, which we prove for lack of a convenient reference.

**Lemma 1.17.** Let $f : X \to G$ be a morphism from an algebraic variety $X$ to a connected commutative algebraic group $G$, both defined over $k$. Let $\chi \in \hat{G}$ be a character. Then the functor $M \mapsto M_\chi$ on $D_c^b(X)$ or $D_c^b(X_{\bar{k}})$ is t-exact. In particular, if $M$ is perverse (resp. semiperverse) then so is $M_\chi$.

**Proof.** Let $i \in \mathbb{Z}$. Since $\mathcal{L}_\chi$ is a lisse sheaf on $G$, the pullback $f^* \mathcal{L}_\chi$ is lisse on $X$, and hence tensoring with $f^* \mathcal{L}_\chi$ is exact for the standard t-structure on $D_c^b(G)$ or $D_c^b(G_{\bar{k}})$ (i.e., the t-structure whose heart is the category of lisse sheaves in degree 0). There are thus canonical isomorphisms $\mathcal{H}^i(M \otimes f^* \mathcal{L}_\chi) \simeq \mathcal{H}^i(M) \otimes f^* \mathcal{L}_\chi$ for all $i$. Hence, looking at the support, we see that the functor $M \mapsto M_\chi$ is right t-exact for the perverse t-structure. It is also left t-exact since $D(M_\chi)$ is isomorphic to $D(M)_{\chi^{-1}}$, hence the result. \hfill $\Box$

### 1.6. Complexity estimates for character sheaves

We keep the notation of the previous section. The first essential new ingredient for our work is the fact that the complexity of character sheaves on $G$ is uniformly bounded.

**Proposition 1.18.** Let $G$ be a connected commutative algebraic group over $k$ with a quasi-projective immersion $u$. There exists a real number $C \geq 0$ such that, for every $n \geq 1$ and for every character $\chi \in \hat{G}(k_n)$, the inequality $c_u(L_\chi) \leq C$ holds.

**Proof.** We will proceed in several steps, noting first that we may assume that $n = 1$.

(1) If the result is true for the groups $G_1$ and $G_2$, then it is true for their product $G = G_1 \times G_2$. Indeed, let $p_i : G \to G_i$ denote the projections. Since any character $\chi$ of $G(k)$ is of the form $(x_1, x_2) \mapsto \chi_1(x_1)\chi_2(x_2)$ for some characters $\chi_i$ of $G_i(k)$, the corresponding character sheaf is the external product $\mathcal{L}_\chi = p_1^* \mathcal{L}_{\chi_1} \boxtimes p_2^* \mathcal{L}_{\chi_2}$, which has complexity bounded in terms of the complexity of $\mathcal{L}_{\chi_1}$ and that of $\mathcal{L}_{\chi_2}$, and hence bounded uniformly by assumption.

(More precisely, this is one case where we use Remark 1.6, since we most easily bound the complexity of $p_1^* \mathcal{L}_{\chi_1} \boxtimes p_2^* \mathcal{L}_{\chi_2}$ with respect to the composition $u$ of the given quasi-projective immersions $u_1$ and $u_2$ of $G_1$ and $G_2$ and the Segre embedding using Theorem 1.5, as in [100, Prop. 6.13]; by Remark 1.6, this is enough.)

(2) If the result holds for a group $G$, then for any finite subgroup scheme $H$ (defined over $k$), the results holds for the quotient $G/H$ (if this quotient is an algebraic group). To see this, we can
further decompose $H = H_r \times H_l$ where $H_r$ is reduced and $H_l$ is local, so that we may assume that $H$ is either reduced or local. Let $v$ be a quasi-projective embedding of $G/H$ and let $\pi : G \to G/H$ be the quotient morphism.

If $H$ is reduced, then $\pi$ is a finite étale covering, so for any lisse sheaf $\mathcal{L}$ on $G/H$, the sheaf $\mathcal{L}$ is a direct factor of $\pi_*\pi^*\mathcal{L}$, and we deduce
\[ c_v(\mathcal{L}) \leq c_v(\pi_*\pi^*\mathcal{L}) \ll c_u(\pi_*\mathcal{L}). \]
This implies the result since $\pi_*\mathcal{L}$ is a character sheaf on $G$ if $\mathcal{L}$ is a character sheaf on $G/H$.

If $H$ is local, then the quotient morphism $\pi$ is radicial, and hence we have $c_v(M) = c_v(\pi^*\mathcal{L})$ for any object $M$ on $G/H$, by Proposition 1.3, and the result again follows.

(3) The result is valid for tori and unipotent groups. For the former, since complexity is a geometric invariant, we may assume that we have a split torus, and the result then follows from (1) and the case of $G = G_m$, which is established in [100, Prop. 7.5].

Assume then that $G$ is a unipotent group. Let $G^\vee$ be its Serre dual (or more precisely, an algebraic group model of it, see Section 2.2 for details). There exists a lisse $\ell$-adic sheaf $\mathcal{L}$ of rank 1 on $G^\vee \times G$ such that the character sheaves associated to characters of $G(k)$ are in bijection with the points $a \in G^\vee(k)$ by mapping $a \in G^\vee(k)$ to the restriction of the sheaf $\mathcal{L}$ to $\{a\} \times G$. Hence, by Theorem 1.5, the complexity of any character sheaf of $G$ is bounded in terms of the complexity of the single sheaf $\mathcal{L}$.

(4) The result holds for abelian varieties by [100, Prop. 7.9], since abelian varieties are projective and any character sheaf is lisse on $G$.

(5) The general case now follows using the previous results and the dévissage of Proposition 1.13.

\[ \square \]

Remark 1.19. A potential alternative (more conceptual) approach to this result would be the following. For a character sheaf $\mathcal{L}$ on $G$, there is an isomorphism
\[ m^*\mathcal{L} \simeq p_1^*\mathcal{L} \boxtimes p_2^*\mathcal{L} \]
(recall that $m$ is the multiplication map $G \times G \to G$). If one could prove directly the estimate
\[ (1.9) \quad c(\mathcal{L})^2 \ll c(p_1^*\mathcal{L} \boxtimes p_2^*\mathcal{L}), \]
then we would deduce from Theorem 1.5 that
\[ c(\mathcal{L})^2 \ll c(m^*\mathcal{L}) \ll c(\mathcal{L}), \]
and hence $c(\mathcal{L}) \ll 1$. Note that Proposition 1.18 shows that (1.9) is indeed true, and it is maybe not out of the question that one could provide a direct proof.

1.7. Arithmetic Fourier transforms

We continue with the notation of the previous section. Given an $\ell$-adic complex $M$ in $D_b^c(G)$, we can consider for any fixed $n \geq 1$ the discrete Fourier transform of the trace function $x \mapsto t_M(x; k_n)$ on $G(k_n)$, which we normalize to be the function from $\hat{G}(k_n)$ to $\overline{\mathbb{Q}}_\ell$, or $\mathbb{C}$, defined by
\[ \chi \mapsto S(M, \chi) = \sum_{x \in G(k_n)} \chi(x)t_M(x; k_n). \]
This Fourier transform satisfies the usual formalism of commutative harmonic analysis (see, e.g., [13]). For instance the Fourier inversion formula

\begin{equation}
    t_M(x; k_n) = \frac{1}{|G(k_n)|} \sum_{\chi \in \hat{G}(k_n)} S(M, \chi) \bar{\chi}(x)
\end{equation}

holds for any \( x \in G(k_n) \), and the Plancherel formula

\begin{equation}
    \sum_{x \in G(k_n)} |t_M(x; k_n)|^2 = \frac{1}{|G(k_n)|} \sum_{\chi \in \hat{G}(k_n)} |S(M, \chi)|^2
\end{equation}

is valid.

Putting together the data of these discrete Fourier transforms on \( G(k_n) \) for all \( n \geq 1 \), we obtain what we call the arithmetic Fourier transform of the complex \( M \), an element of the product set

\( \prod_{n \geq 1} \mathcal{C}(\hat{G}(k_n), \overline{\mathbb{Q}}_\ell), \)

where, for any set \( X \) and ring \( A \), we denote by \( \mathcal{C}(X, A) \) the \( A \)-module of functions \( f : X \rightarrow A \).

Combining the Fourier inversion formula (1.10) with the known injectivity theorem for trace functions (see Proposition A.22), we deduce a corresponding injectivity property of the discrete Fourier transform of complexes:

**Proposition 1.20.** Let \( M_1 \) and \( M_2 \) be complexes in \( D^b_{\text{c}}(G) \) such that for all \( n \geq 1 \) and all characters \( \chi \in \hat{G}(k_n) \), we have the equality

\[ \sum_{x \in G(k_n)} \chi(x) t_{M_1}(x; k_n) = \sum_{x \in G(k_n)} \chi(x) t_{M_2}(x; k_n). \]

Then the classes of \( M_1 \) and \( M_2 \) in the Grothendieck group \( K(G) = K(G, \overline{\mathbb{Q}}_\ell) \) are equal.

**Remark 1.21.** In Chapter 7, we will establish a more refined statement where the equality of discrete Fourier transforms is only assumed to hold for characters in a “generic” set, as described below.

### 1.8. Generic sets of characters

For an arbitrary connected commutative algebraic group, there is no obvious topology (or measure) on the set \( \hat{G} \) of characters which would lead to a natural notion of sets containing “almost all” characters. We will use instead the following definition of a generic set of characters.

**Definition 1.22.** Let \( k \) be a finite field and let \( G \) be a connected commutative algebraic group of dimension \( d \) over \( k \). Let \( S \) be a subset of \( \hat{G} \).

Let \( i \geq 0 \) be an integer. We say that \( S \) has character codimension at least \( i \), which we denote sometimes by \( \text{ccodim}(S) \geq i \), if the estimate

\begin{equation}
    |S(k_n)| \ll |k|^n(d-i)
\end{equation}

holds for all integers \( n \geq 1 \).

We say that \( S \) is *generic* if \( \hat{G} \rightarrow S \) has character codimension at least 1, i.e., if the estimate

\begin{equation}
    \left| \hat{G}(k_n) \rightarrow S(k_n) \right| \ll |k|^n(d-1)
\end{equation}

holds for all integers \( n \geq 1 \).
We now discuss the relation between the definition of generic sets and other notions that appear in the literature, in the case of unipotent and semiabelian varieties.

If \( G \) is unipotent, then the set of characters can be identified with the \( \bar{k} \)-points of a \( k \)-scheme \( G' \), see again Section 2.2. If \( S \subset \tilde{G} \) is algebraic (i.e., if it is the disjoint union of the sets \( \tilde{S}(k_n) \) for some subvariety \( S \) of \( G \)), then the condition \( \text{codim}(S) \geq i \) implies that the codimension of \( S \) in \( G \) is at least \( i \). Conversely, if \( S \) is a closed subvariety of \( G \), defined over \( k \), then \( \text{codim}(\tilde{S}(k)) \geq \text{codim}_G(\tilde{S}) \).

Let \( G \) be a semiabelian variety over \( k \). Let \( \ell \) be a prime different from the characteristic of \( k \). The set of \( \ell \)-adic characters of \( G \) can be naturally identified with the set of \( \bar{Q}_\ell \)-points of \( \tilde{G} \), as we now recall.

Let \( \pi_1(G_k) \) be the geometric tame étale fundamental group of \( G \) (see for instance the paper [75]) of Kerz and Schmidt for various equivalent definitions; note that it is well-known that semiabelian varieties have good compactifications), and let \( \Pi(G, \bar{Q}_\ell) \) be the group of continuous characters \( \chi : \pi_1(G_k) \to \bar{Q}_\ell^\times \). For any \( n \geq 1 \) and any character \( \chi \in \tilde{G}(k_n) \), the character sheaf \( \mathcal{L}_\chi \) is tamely ramified (indeed, only the case of tori requires proof; since the question is geometric, we may assume that \( G = \mathbb{G}_m^d \) for some integer \( d \geq 0 \), and the result follows by induction from the well-known case of \( \mathbb{G}_m \) and the multiplicativity of the tame fundamental group, for which see, e.g., [96, Th. 5.1]), and hence corresponds to a point in \( \Pi(G, \bar{Q}_\ell) \). This leads to a natural injective map

\[
\tilde{G} \hookrightarrow \Pi(G, \bar{Q}_\ell),
\]

and we will identify \( \tilde{G} \) this way with a subset of \( \Pi(G, \bar{Q}_\ell) \).

We have a decomposition \( \Pi(G, \bar{Q}_\ell) = \Pi(G, \bar{Q}_\ell)_{\ell'} \times \Pi(G, \bar{Q}_\ell)_{\ell} \), where \( \Pi(G, \bar{Q}_\ell)_{\ell'} \) is the group of torsion characters of order prime to \( \ell \) and \( \Pi(G, \bar{Q}_\ell)_{\ell} \) is the group of characters that factor through the maximal pro-\( \ell \) quotient \( \pi_1(G_k)_{\ell} \) of \( \pi_1(G_k) \). Since \( \pi_1(G_k)_{\ell} \) is a free \( \mathbb{Z}_\ell \)-module of finite rank, by a result of Brion and Szamuely [17], we can identify \( \Pi(G, \bar{Q}_\ell)_{\ell} \) with the \( \bar{Q}_\ell \)-points of a scheme \( \Pi(G, \bar{Q}_\ell)_{\ell} \), following the arguments of Gabber and Loeser in [46, Section 3.3].

Let then \( \Pi(G) \) be the disjoint union of the schemes \( \Pi(G)_{\ell} \) indexed by \( \chi \in \Pi(G, \bar{Q}_\ell)_{\ell'} \). We have then

\[
\Pi(G, \bar{Q}_\ell) = \Pi(G)(\bar{Q}_\ell),
\]

and as above we will identify \( \tilde{G} \) with a subset of \( \Pi(G)(\bar{Q}_\ell) \).

Let \( G' \) be a semiabelian variety over \( \bar{k} \) and \( f : G \to G' \) a homomorphism. Then we have a dual morphism \( \Pi(G') \to \Pi(G) \), which we denote by \( \chi \mapsto \chi' \circ f \); if \( f \) is an inclusion, we also write simply \( \chi' = \chi' |_G \). The restriction of this map to the subset \( \tilde{G}' \) is the map \( \tilde{f} : \tilde{G}' \to \tilde{G} \) defined previously.

**Definition 1.23.** Let \( G \) be a semiabelian variety over a finite field \( k \), and let \( \ell \) be a prime different from the characteristic of \( k \).

1. A subset \( S \subset \Pi(G)(\bar{Q}_\ell) \) is a *translate of an algebraic cotorus* (abbreviated tac) if there exists a surjective morphism of semiabelian varieties \( \pi : G_k \to G'_k \), with non-trivial connected kernel, and a character \( \chi_0 \in \Pi(G)(\bar{Q}_\ell) \) such that

\[
S = \{ \chi_0 \cdot (\chi' \circ \pi) \in \Pi(G)(\bar{Q}_\ell) \mid \chi' \in \Pi(G')(\bar{Q}_\ell) \}. \]

We then say that \( S \) is *defined by the quotient* \( G_k \to G'_k \) and the character \( \chi_0 \), and we say that \( S \) *has dimension* \( \dim(G'_k) \). The kernel of \( \pi \) is also called the *kernel of the tac*. If the quotient morphism is defined over a finite extension \( k' \) of \( k \), then we say that \( S \) is a tac of \( G_{k'} \).
(2) We say that a subset $S \subset \Pi(G)({\overline{Q}}_{\ell})$ contains *most* characters if the complement of $S$ is contained in a finite union of tacs.

(3) We say that a subset $S \subset \Pi(G)({\overline{Q}}_{\ell})$ is *weakly generic* if it is a generic set in the sense of the Zariski topology in $\Pi(G)$.

By extension, we shall say that a subset $S \subset \hat{G}$ contains *most* characters, or is *weakly generic*, if its image in $\Pi(G)({\overline{Q}}_{\ell})$ satisfies this property.

**Remark 1.24.** (1) The terminology "most" is used by Kr"amer and Weissauer [84]; Esnault and Kerz [33] speak of "quasi-linear" subsets. What we call "weakly generic" is usually called "generic" (see for example the papers [84], [81] and [46]).

(2) Let $S \subset \Pi(G)({\overline{Q}}_{\ell})$ be a subset that contains most characters. The Lang–Weil estimates imply that $S \cap \hat{G}$ is generic. Also, if $S \subset \hat{G}$ is a generic set and $\Pi(G)({\overline{Q}}_{\ell}) - S$ is not Zariski-dense, then $S$ is weakly generic.

(3) The tac defined by $\pi$ and $\chi_0$ can also be interpreted as the set of characters $\chi$ such that the restriction of $\chi$ to $\ker(\pi)$ is equal to that of $\chi_0$.

(4) If a tac $S$ has dimension $i$, then $S \cap \hat{G}$ has character codimension $\geq \dim(G) - i$ since
\[
|\{S \cap \hat{G}\}(k_n)| \leq |G'(k_n)| \ll |k|^ni
\]
if $S$ is defined by the quotient $G \to G'$ and the character $\chi_0$.

**Lemma 1.25.** Let $G$ be a semiabelian variety over a finite field $k$. Let $\ell$ be a prime different from the characteristic of $k$. Let $I$ be a non-empty finite set and let $(S_i)_{i \in I}$ be a family of tacs in $G$, defined by quotient morphisms $\pi_i: G_k \to G_{i,k}$ and characters $\chi_i \in \Pi(G)({\overline{Q}}_{\ell})$.

Let $K$ be the subgroup of $G_k$ generated by the subgroups $\ker(\pi_i)$. The intersection $S = \bigcap S_i$ is not empty if and only if the restriction of $\chi_i$ to $K$ is independent of $i$.

*If this is the case, then $S$ is a tac, which is defined by the quotient morphism $\pi: G_k \to G_k/K$ and any of the characters $\chi_i$."

**Proof.** We denote $K_i = \ker(\pi_i)$ for $i \in I$. Since each $K_i$ is connected by definition, the subgroup $K$ generated by the $K_i$ is also connected.

Let $\chi \in \Pi(G)({\overline{Q}}_{\ell})$. We have $\chi \in S_i$ if and only if $\chi | K_i = \chi_i | K_i$, hence if $\chi \in S$, the restriction of $\chi_i$ to $K$ must coincide with the restriction of $\chi$ to $K_i$ and is therefore independent of $i$.

Conversely, if this condition is satisfied, then pick any $i_0 \in I$. The tac defined by $G_k \to G_k/K$ and the character $\chi_{i_0}$ consists of characters $\chi$ such that $\chi | K = \chi_{i_0} | K$. This condition is equivalent to $\chi | K_i = \chi_{i_0} | K_i$ for all $i \in I$. Since $\chi_i | K_i = \chi_{i_0} | K_i$, we see that this tac is exactly the intersection of the $S_i$.\]

**1.9. Fourier–Mellin transforms on semiabelian varieties**

Let $k$ be a finite field and $G$ a semiabelian variety over $k$. Let $\ell$ be a prime different from the characteristic of $k$. We use the notation of the previous section.

We recall here some results of Gabber and Loeser for tori [46], generalized by Krämer [81] to semiabelian varieties.

Let $R$ be the ring of integers of a finite extension of $Q_\ell$ and $\Omega_G = R[\pi_1'(G_k)_\ell]$. We have $\Pi(G)_\ell = \text{Spec}(Q_\ell \otimes_R \Omega_G)$.

Let $p: G_k \to \text{Spec}(k)$ be the structural morphism. We denote by $\text{can}_G$ the tautological character $\text{can}_G: \pi_1'(G_k)_\ell \to \Omega_G^x$.\]

29
which defines a lisse \( \Omega^\text{G} \)-sheaf of rank one on \( \overline{G}_k \), which we denote \( L^\text{G}_\ell \). Given a complex \( N \in D^b_c(\overline{G}_k, \mathbb{R}) \), one can define the Fourier-Mellin transforms of \( N \), with and without compact support, as the objects

\[
FM_!(N) = R\pi!(N \otimes_\mathbb{R} \mathcal{L}_G) \in D^b_c(\overline{G}_k, \Omega^\text{G}) = D^b_{\text{coh}}(\Omega^\text{G})
\]

and

\[
FM_*(N) = R\pi^*(N \otimes_\mathbb{R} \mathcal{L}_G) \in D^b_{\text{coh}}(\Omega^\text{G}).
\]

Inverting \( \ell \) and passing to the direct limit over all extensions \( R \subset \overline{Q}_\ell \) and all \( \chi \in \Pi(G, \overline{Q}_\ell)^\vee \), we then get two functors

\[
FM_!, FM_* : D^b_c(\overline{G}_k) \to D^b_{\text{coh}}(\Pi(G)),
\]

where \( D^b_{\text{coh}}(\Pi(G)) \) is the derived category of the category of coherent sheaves on \( \Pi(G) \).

By (the generalization of) [46, Cor. 3.3.2], for \( N \in D^b_c(\overline{G}_k) \) and every \( \chi \in \Pi(G)(\overline{Q}_\ell) \), viewed as a closed immersion \( i_\chi : \{\chi\} \to \Pi(G) \), we have canonical isomorphisms

\[
L_{i_\chi}^*FM_!(N) \simeq R\pi!(N_\chi) \quad \text{and} \quad L_{i_\chi}^*FM_*(N) \simeq R\pi^*(N_\chi),
\]

where \( L_{i_\chi} \) indicates left-derived functors.

### 1.10. A geometric lemma

We will use the following lemma in the proof of the general higher vanishing theorem.

A connected commutative algebraic group \( G \) is said to be almost simple if it has no proper connected closed subgroup. Examples of such groups are \( \mathbb{G}_a \), \( \mathbb{G}_m \) and simple abelian varieties.

**Lemma 1.26.** Let \( k \) be a field. Let \( s \geq 0 \) be an integer. We denote \( [s] = \{1, \ldots, s\} \). Let

\[
G = \prod_{i=1}^s G_i
\]

be a product of almost simple connected commutative algebraic groups over \( k \). Let \( d = \dim(G) \).

For any subset \( I \subset [s] \), let

\[
G_I = \prod_{i \in I} G_i,
\]

which we identify with a subgroup of \( G \) in the obvious way.

Let \( 1 \leq i \leq d \). Let \( \mathcal{E}_i \) be the set of subsets \( I \) such that \( \dim(G_I) > d - i \). For each \( I \in \mathcal{E}_i \), let \( H_I \) be a non-trivial subgroup of \( G_I \). Then the algebraic subgroup generated by all \( H_I \) has dimension at least \( i \).

**Proof.** We denote \( d_i = \dim(G_i) \) for \( 1 \leq i \leq s \).

We work by induction on \( s \), and for each \( s \), by induction on \( i \). The case \( s = 1 \) is elementary, since \( H_{[s]} = G \) in that case. For any \( s \), the result is also clear for \( i = 1 \), since we then have \( H = G \) and \( \dim(A_G) \geq 1 \). Assume now that \( 2 \leq i \leq g \) and that the result is known for \( (s, i') \) for \( i' < i \) as well as for \( (s', i) \) for any \( s' < s \).

The subgroup \( H_{[s]} \subset G \) is non-trivial, and hence there exists some integer \( j \leq s \) such that the image of \( H_{[s]} \) under the projection \( G \to G_j \) is non-trivial; this means that this image must be equal to \( G_j \) since all \( G_i \) are almost simple. Up to reordering the factors, we may assume that the projection of \( H_{[s]} \) on \( G_s \) is surjective.

If \( g_s \geq i \), then we are done since we then have \( \dim(I) \geq \dim(H_{[s]}) \geq \dim(G_s) = d_s \geq i \). We therefore assume now that \( d_s < i \).
Let \( G' = G_1 \times \cdots \times G_{s-1} \) and \( i' = i - d_s \). The dimension of \( G' \) is \( d' = d - d_s \). We have 
\[ 1 \leq i' \leq d' \text{ and } d - i = d' - i'. \] 
Each \( J \subset \{ s - 1 \} \) with \( \dim(G'_J) > d' - i' = d - i \) is an element of \( \mathcal{E}_i \).
By induction, applied to the subgroups \( H_J \) for \( J \in \mathcal{E}_i' \), the subgroup \( H' \) of \( G' \) generated by all \( H_J \) has dimension \( \geq i' = i - d_s \).

To conclude, we observe that since \( H' \) is a subgroup of \( G' \) with dimension \( \geq i - d_s \) and \( H_{[a]} \) is a subgroup of \( G = G' \times G_s \) such that the projection of \( H_{[a]} \) to \( G_s \) is surjective, the subgroup \( H \) that they generate together satisfies

\[
\dim(H) = \dim(H') + \dim(H_{[a]}) - \dim(H' \cap H_{[a]}) \\
\geq \dim(H') + \dim(H_{[a]}) - \dim(G' \cap H_{[a]}) = i - d_s + d_s = i
\]

since \( \dim(G' \cap H_{[a]}) + \dim(G_s) = \dim(H_{[a]}) \).

\[ \square \]

1.11. Geometric and arithmetic semisimplicity

Let \( k \) be a finite field, and \( \bar{k} \) and algebraic closure of \( k \). Let \( \ell \) be a prime different from the characteristic of \( k \).

For an algebraic variety \( X \) over \( k \) and a complex \( M \) in \( \text{D}^b_c(X, \overline{\mathbb{Q}}_\ell) \), we will sometimes refer to properties of \( M \) (e.g., \( M \) being a simple or semisimple perverse sheaf) as arithmetic, and to the analogue for the base change of \( M \) to \( M_{\bar{k}} \) as being geometric. Thus we may speak of a geometrically simple perverse sheaf, or an arithmetically semisimple perverse sheaf.

We collect here some facts about certain relations between such properties.

**Lemma 1.27.** Let \( X \) a geometrically irreducible algebraic variety over \( k \) and \( \mathcal{F} \) a lisse \( \ell \)-adic sheaf on \( X \). If \( \mathcal{F} \) is arithmetically semisimple, then it is geometrically semisimple.

**Proof.** Using the correspondence between lisse sheaves and representations of the étale fundamental group, this follows, e.g., from [106, Lem. 5 (a)]. \[ \square \]

**Lemma 1.28.** Let \( (X, u) \) be a quasi-projective variety over \( k \). Let \( M \) be an arithmetically simple perverse sheaf on \( X \). There exists a finite extension of \( k \) of degree bounded in terms of \( c_u(M) \) such that the base change of \( M \) to \( X_{k'} \) is a direct sum of geometrically simple perverse sheaves on \( k' \).

In particular, \( M \) is geometrically semisimple.

**Proof.** By [6, Prop. 5.3.9 (ii)], there exists an integer \( n \geq 1 \) and a geometrically simple perverse sheaf \( N \) on \( X_{k_n} \) such that \( M = f_n N \), where \( f_n : X_{k_n} \to X \) is the base change morphism. Since \( N \) is non-zero, we deduce that \( n \ll c_u(M) \) by looking at the rank at a generic point of the support. The base change of \( M \) to \( k_n \) is then a direct sum of geometrically simple perverse sheaves. \[ \square \]

**Lemma 1.29.** Let \( k \) be a finite field and \( \bar{k} \) an algebraic closure of \( k \). Let \( \ell \) be a prime different from the characteristic of \( k \). Let \( X \) be a smooth and geometrically connected quasi-projective variety over \( k \). Two arithmetically simple perverse sheaves on \( X \) are geometrically isomorphic if and only if there exists \( \alpha \in \overline{\mathbb{Q}}_\ell \) such that \( M \simeq \alpha^\text{deg} \otimes N \).

This is a standard fact (see, e.g., [91, Lemme 4.4.4]).

1.12. A result from representation theory

The following basic fact from representation theory of reductive groups will play a crucial role.
Proposition 1.30. Let $F$ be a field of characteristic zero and let $G$ be a reductive algebraic group over $F$. Let $V$ be a finite-dimensional faithful representation of $G$ over $F$. Any finite-dimensional irreducible representation of $G$ over $F$ occurs in a tensor power $(V \oplus V^\vee)^\otimes m$ for some integer $m \geq 0$, where $V^\vee$ is the contragredient of $V$.

See, for instance, [28, Prop. 3.1] for the proof.
CHAPTER 2

Generic vanishing theorems

Throughout this chapter, $k$ denotes a finite field, $\bar{k}$ an algebraic closure of $k$, and $k_n$ the extension of degree $n$ of $k$ inside $\bar{k}$ for each $n \geq 1$. We also fix once for all a prime number $\ell$ different from the characteristic of $k$. All complexes of sheaves and characters are tacitly understood to be $\ell$-adic complexes and characters for this choice of $\ell$.

2.1. Statement of the vanishing theorems

We now state our main vanishing theorems.

THEOREM 2.1 (Generic vanishing). Let $G$ be a connected commutative algebraic group over $k$ and let $M$ be a perverse sheaf on $G$. The set of characters $\chi \in \widehat{G}$ satisfying

\begin{equation}
\begin{align*}
H^i(\bar{k}, M_\chi) &= H^i_c(\bar{k}, M_\chi) = 0 & \text{for all } i \neq 0, \\
H^0_c(\bar{k}, M_\chi) &= H^0(\bar{k}, M_\chi)
\end{align*}
\end{equation}

is generic in the sense of Definition 1.22.

This gives the first part of Theorem 1 from the introduction.

REMARK 2.2. Various versions of Theorem 2.1 have been proved by the following authors:

1. Katz–Laumon [71, Th. 2.1.3, Scholie 2.3.1] in the case of powers of the additive group and Saibi [99, Th. 3.1] in the case of unipotent groups; in both cases, the generic set is a Zariski-dense open subset of the $k$-scheme parameterizing characters.

2. Gabber–Loeser [46, Cor. 2.3.2] for tori, with “generic” replaced by a condition implying “weakly-generic” in the sense of Definition 1.23; see also [46, Th. 7.2.1], for “most” characters in codimension 1.

3. Weissauer [113, Vanishing Th., p. 561] for abelian varieties, with “generic” replaced by “most”, and Krämer [81, Th. 2.1] for semiabelian varieties, with “weakly generic” characters.

We will in fact prove the following stronger result, which also controls the “stratification” arising from the non-vanishing of other cohomology groups; this has a number of useful applications.

THEOREM 2.3 (Stratified vanishing). Let $G$ be a connected commutative algebraic group of dimension $d$ over $k$, and $M$ a perverse sheaf on $G$. There exist subsets

$$\mathcal{I}_d \subset \cdots \subset \mathcal{I}_0 = \widehat{G}$$

such that the following holds:

1. For $0 \leq i \leq d$, the subset $\mathcal{I}_i$ has character codimension at least $i$. 

For $0 \leq i \leq d$, any $\chi \in \hat{G}$ such that at least one of the cohomology groups
\begin{equation}
\begin{aligned}
H^i(G, M_\chi), \quad H^{-i}(G, M_\chi), \quad H^c_i(G, M_\chi), \quad H^{-c}_i(G, M_\chi)
\end{aligned}
\end{equation}
is non-zero belongs to $S_i$.

For $\chi \in S_0 S_1$, the equality $H^0_c(G, M_\chi) = H^0(G, M_\chi)$ holds.

If $G$ is a torus or an abelian variety, then $S_i$ is a finite union of tacs of $G$ of dimension $\leq d - i$.

If $G$ is a unipotent group, then $S_i$ is the set of closed points of a closed subvariety of dimension $\leq d - i$ of the Serre dual $G^\vee$.

Concretely, this implies that for $0 \leq i \leq d$, the estimate
$$|\{\chi \in \hat{G}(k_n) \mid H^c_i(G, M_\chi) \neq 0 \text{ or } H^{-c}_i(G, M_\chi) \neq 0 \text{ or } H^i(G, M_\chi) \neq 0 \text{ or } H^{-i}(G, M_\chi) \neq 0\}| \ll |k_n|^{d-i}$$
holds for all $n \geq 1$, and so this implies the second part of Theorem 1.

Note that Theorem 2.1 is a straightforward consequence of Theorem 2.3, since the set of characters satisfying (2.1) contains the generic set $S_0 S_1$.

Remark 2.4. We expect that this result should be true with the stronger information that the implied constants in (1.11) for the subsets $S_i$ depend only on the complexity of $M$. A result of this type would be especially useful for applications to “horizontal” equidistribution theorems.

However, we can only prove this at the current time in the following cases:

(1) if $G$ is a unipotent group (use the equality of Fourier transforms of [99, Th. 3.1] combined with Theorem 1.7);

(2) if $G$ is a geometrically simple abelian variety (see Corollary 2.19);

(3) and probably, although we have not checked this in full details, if $G = U \times G_m$ where $U$ is unipotent.

The issues that arise in attempting to handle the general case are:

- For tori, the use of de Jong’s theorem on alterations, where we do not control the number of exceptional components that appear (thus, a suitably effective version of de Jong’s theorem, or an effective form of embedded resolution of singularities, would probably imply the desired conclusion in this case).

- For abelian varieties, the need to find and control the complexity of an alteration that “moderates” certain perverse sheaves, to apply results of Orgogozo.

Corollary 2.5. Let $G$ be a connected commutative algebraic group over $k$. Let $M$ be an object of $D^b_c(G)$. Then for generic $\chi \in \hat{G}$ and any $i \in \mathbb{Z}$, we have canonical isomorphisms
$$H^i_c(G, M_\chi) \simeq H^i_c(G, M_\chi) \simeq H^0_c(G, M_\chi) \simeq H^0_c(G, \mathcal{H}_i(M_\chi)).$$

Proof. The proof is similar to that of [81, Cor. 2.3]; see the proof of Corollary 2.18 below for a similar statement.

We will prove Theorem 2.3 in Section 2.5. Before doing this, we need to establish some preliminaries concerning perverse sheaves on the basic building blocks of Proposition 1.13, namely (in rough order of difficulty) unipotent groups, tori and abelian varieties.

Note that proving either Theorem 1 or Theorem 2 for a given group $G$ only involves the corresponding material for groups of the types which actually appear in Proposition 1.13 applied
to G. In particular, for instance, the proof of Theorem 3 (and other similar statements) only depends on the case of tori, i.e., on Section 2.3.

To facilitate orientation, we list below the key statements about each type of groups; Section 2.5 only requires these statements from the next three sections.

1. Unipotent groups: Proposition 2.7.
2. Tori: Corollary 2.15.
3. Abelian varieties: Corollary 2.28 and the auxiliary Theorem 2.25, due to Orgogozo [97].

2.2. The case of unipotent groups

We begin by summarizing the duality theory of commutative unipotent groups; a good account can also be found in [14, App. F].

Let U be a connected unipotent commutative algebraic group over a finite field $k$ of characteristic $p$. The functor that sends a perfect $k$-scheme $S$ (i.e., a scheme for which the absolute Frobenius is an automorphism) to the extension group

$$\text{Ext}^1(U \times_k S, Q_p/Z_p) = \lim_{\rightarrow} \text{Ext}^1(U \times_k S, p^{-m}Z_p/Z_p)$$

in the category of commutative group schemes over $S$ (with $Q_p/Z_p$ viewed as a constant group scheme) is representable by a connected commutative group scheme $U^*$ over $k$, called the Serre dual of U. This goes back to a remark by Serre [104, p. 55] and was developed by Bégueri in [5, Prop. 1.2.1] and Saibi [99]. Moreover, if $m \geq 1$ is such that $p^mU = 0$, then the natural morphism

$$\text{Ext}^1(U \times_k S, p^{-m}Z_p/Z_p) \to \lim_{\rightarrow} \text{Ext}^1(U \times_k S, p^{-m}Z_p/Z_p)$$

is an isomorphism.

Let $A$ be a finite abelian group. For each integer $n \geq 1$, the short exact sequence

$$1 \to U(k_n) \to U_k \xrightarrow{x \mapsto \text{Fr}_k(x) \cdot x^{-1}} U_{k_n} \to 1$$

induces an isomorphism

$$\text{Hom}(U(k_n), A) \to \text{Ext}^1(U_{k_n}, A)$$

(see [14, Prop. F.2]).

Let $m \geq 1$ be such that $p^mU = 0$. We take $A = p^{-m}Z_p/pZ_p \simeq Z/p^mZ$. For any integer $n \geq 1$, we obtain an isomorphism

$$U^*(k_n) \to \text{Ext}^1(U_{k_n}, A) \to \text{Hom}(U(k_n), A).$$

Fix now a faithful character $\psi: p^{-m}Z_p/Z_p \to \mathbb{Q}_\ell^\times$. We then obtain, for any $n \geq 1$, an isomorphism

$$U^*(k_n) \to \widehat{U}(k_n).$$

Saibi [99, Lemma 1.5.4.1] (see also [14, Remark F.1 (ii)]) proved that there exists a connected commutative unipotent algebraic group $U^\vee$ and a bi-extension $\mathcal{E}_{U^\vee}^\vee$ of $U^\vee \times U$ by $Q_p/Z_p$ such that the bi-extension induces an isomorphism between the perfectization of $U^\vee$ and $U^*$. Together with the above character $\psi$, this induces isomorphisms

$$\beta_n: U^\vee(k_n) \to \widehat{U}(k_n)$$

for all $n \geq 1$. (See also [14, Remark F.4 (ii)] for a different approach to the construction of the finite-type model $U^\vee$.) We also write $\hat{\psi}_x$ for the character $\beta_n(x).$
We denote by $\mathcal{L}_{U, U^\lor, \psi}$ the associated lisse $\ell$-adic sheaf of rank 1 on $U^\lor \times U$; its trace functions are given by

$$t_n(x, y; k_n) = \beta_n(x)(y)$$

for all $n \geq 1$ and $(x, y) \in U(k_n) \times U^\lor(k_n)$.

**Example 2.6.** Fix a non-trivial additive character $\psi: k \to \overline{Q}_\ell$. Suppose that $U = G^d_a$ for some $d \geq 0$. We denote

$$x \cdot y = \sum_{i=1}^d x_i y_i$$

for $(x, y) \in U \times U$.

There exists a choice of bi-extension with $U^\lor = U$, and the isomorphisms

$$\beta_n: (G^d_a)(k_n) \to \hat{G}^d_a(k_n)$$

are given by $x \mapsto \psi(x)$ where

$$\psi(x)(y) = \psi(\text{Tr}_{k_n/k}(x \cdot y)).$$

We come back to the general case. Let $p: U \times_k U^\lor \to U$ and $p^\lor: U \times_k U^\lor \to U^\lor$ denote the projections to both factors. The **Fourier transform** is the functor $\text{FT}_\psi: D^b_c(U) \to D^b_c(U^\lor)$ defined by

$$\text{FT}_\psi(M) = R\text{p}^\lor_!(p^* M \otimes \mathcal{L}_{U, U^\lor, \psi}) = R\text{p}^\lor_* (p^* M \otimes \mathcal{L}_{U, U^\lor, \psi}),$$

where the second equality (more precisely, the fact that the natural transformation “forget supports” from the left-hand side to the right-hand side is an isomorphism) is [99, Th. 3.1]. A corollary of this is that the Fourier transform is compatible with Verdier duality, in that there is a canonical functorial isomorphism

$$\text{D}(\text{FT}_\psi(M)) \simeq \text{FT}_\psi^{-1}(\text{D}(M))(\dim U)$$

for each object $M$ of $D^b_c(U)$, see [99, Cor. 3.2.1]. We refer the reader to Saibi’s article [99] for the other main properties of the $\ell$-adic Fourier transform on unipotent groups.

By the proper base change theorem and the definition of Fourier transform using $p^\lor_!$, for all $a \in U^\lor(\overline{k})$ and $i \in \mathbb{Z}$, there are natural isomorphisms

$$H^i_c(U_{\overline{k}}, M_{\psi_a}) = \mathcal{H}^i(\text{FT}_\psi(M))_a.$$  

Since unipotent groups are affine, it follows from Artin’s vanishing theorem that the Fourier transform shifts the perverse degree by the dimension of $U$. In particular, if $M$ is perverse, then so is $\text{FT}_\psi(M)[\dim(U)]$.

**Proposition 2.7.** Let $U$ be a connected unipotent commutative algebraic group of dimension $d$ over $k$. Fix a locally-closed immersion $u$ of $U$ into some projective space to compute the complexity. Let $M$ be an object of $D^b_c(U)$ of perverse amplitude $[a, b]$.

There exists an integer $C \geq 0$, depending only on $c_u(M)$, and a stratification $(S_i)$ of $U^\lor$ such that every stratum $S_i$ is either empty or has dimension $d - i$, with the following properties:

1. The sum of the degrees of the irreducible components of $u(S_i)$ is at most $C$.
2. For each $a \in S_i(\overline{k})$, the vanishing $H^j_c(U_{\overline{k}}, M_{\psi_a}) = 0$ holds for all $j \notin [a, b + i]$.

In particular, the estimate

$$|S_i(k_n)| \ll |k_n|^{d-i}$$

holds for all $n \geq 1$, with an implicit constant that only depends on $c_u(M)$.  

36
Moreover, for any \( a \in S_0(\bar{k}) \) and any \( j \in \mathbb{Z} \), we have

\[
H^j_c(U_k, M_{\psi_a}) = H^j(U_k, M_{\psi_a}).
\]

**Proof.** Since the Fourier transform shifts the perverse degree by \( d \), the complex \( \text{FT}_\psi(M) \) has perverse amplitude \( [a + d, b + d] \). By Theorem 1.5, the complexity \( c_a(\text{FT}_\psi(M)) \) is bounded in terms of \( c_u(M) \).

By Theorems 1.7 and 1.8, there exists a smooth open subscheme \( S_0 \subset U^\vee \), with closed complement \( Y_0 \) of degree bounded in terms of \( c_u(\text{FT}_\psi(M)) \), and hence in terms of \( c_u(M) \), such that the restriction of \( \text{FT}_\psi(M) \) to \( S_0 \) has lisse cohomology sheaves and such that \( \text{FT}_\psi(M) \) is of formation compatible with any base change \( S' \to S_0 \subset U^\vee \) (this follows from the formula for the Fourier transform in terms of \( p^\vee \)). Up to replacing \( S_0 \) by a smaller open subset we may assume that \( S_0 \) is affine (and this does not increase the complexity of the complement).

In particular, using (2.3) and this compatibility, we obtain the following equality for \( a \in S_0(\bar{k}) \):

\[
H^j_c(U_k, M_{\psi_a}) = \mathcal{H}^j(\text{FT}_\psi(M))_a = H^j(U_k, M_{\psi_a}).
\]

By a slight generalization of [6, Cor. 4.1.10. ii], the pullback by a closed immersion of a complex of perverse amplitude \( [a, b] \) has perverse amplitude \( [a - 1, b] \). Therefore, the restriction of \( \text{FT}_\psi(M) \) to \( Y_0 \) has perverse amplitude \( [a + d - 1, b + d] \). Proceeding by induction, we construct a stratification \( (S_i)_{0 \leq i \leq d} \) of \( U^\vee \) into strats \( S_i \) such that

1. each \( S_i \) is smooth, empty or equidimensional of dimension \( d - i \);
2. the closure of each \( S_i \) has degree bounded in terms of \( c_u(M) \);
3. the restriction of \( \text{FT}_\psi(M) \) to each \( S_i \) has lisse cohomology sheaves and is of perverse amplitude \( [a + d - i, b + d] \).

Let \( 0 \leq i \leq d \). On each connected component of \( S_i \), the support of the cohomology sheaves of \( \text{FT}_\psi(M) \) is either empty or equal to \( S_i \) (since these sheaves are lisse). However, the definition of perversity implies the inequality

\[
\dim \text{supp} \mathcal{H}^j(\text{FT}_\psi(M)|_{S_i}) \leq -j + b + d
\]

for all integers \( j \). Since \( S_i \) has dimension \( d - i \), the non-vanishing of \( \mathcal{H}^j(\text{FT}_\psi(M)|_{S_i}) \) implies therefore the inequality

\[
d - i \leq -j + b + d, \quad \text{i.e.} \quad j \leq b + i.
\]

Since \( S_i \) is smooth of dimension \( d - i \) (so the dualizing complex on \( S_i \) is \( \overline{Q}_d[d-i](d-i) \) and the Verdier dual of a lisse sheaf is the naive dual) and the cohomology sheaves on \( S_i \) are lisse, duality implies that \( D(\text{FT}_\psi(M)|_{S_i}) \) also has lisse cohomology sheaves, given by the formula

\[
\mathcal{H}^j(D(\text{FT}_\psi(M)|_{S_i})) = (\mathcal{H}^{-j+2d-2i}(\text{FT}_\psi(M)|_{S_i}))^\vee(d-i)
\]

for all \( j \).

Thus, arguing as above, the perversity condition shows that the condition \( \mathcal{H}^j(\text{FT}_\psi(M)|_{S_i}) \neq 0 \) implies

\[
d - i \leq j + 2d - 2i - a - d + i, \quad \text{i.e.} \quad j \geq a.
\]

We conclude that the cohomology sheaves of the complex \( \text{FT}_\psi(M)|_{S_i} \) are concentrated in degrees \([a, b + i]\). By proper base change, this implies assertion (2) of the proposition and concludes the proof. \( \square \)
Remark 2.8. This result is a generalization to all unipotent groups, and a quantification by means of the complexity, of some of the Fouvry–Katz–Laumon stratification results for additive exponential sums [71, 35]. It may have interesting applications to analytic number theory, since the quantitative form means that it may be used over varying finite fields, e.g. \( \mathbb{F}_p \) as \( p \to +\infty \); see Chapter 6.

2.3. Perverse sheaves on tori

In this section, we generalize some of the results of Gabber and Loeser [46] about perverse sheaves on tori. We begin with a generalization of [46, Th. 4.1.1’], which is proved in loc. cit. under the assumption that resolution of singularities and simplification of ideals hold for varieties of dimension at most the dimension of the torus in question. The structure of our proof is the same, but we are able to replace the appeal to resolution of singularities with de Jong’s theorem on alterations [23].

Theorem 2.9. Let \( T \) be a torus over \( \tilde{k} \) and let \( M \) be an object of \( D^b_c(T) \). For all characters \( \chi \in \Pi(T(\overline{\mathbb{Q}})) \) outside of a finite union of tacs, the equality \( H^i(T, M_\chi) = H^i_c(T, M_\chi) \) holds for all \( i \in \mathbb{Z} \).

As in [46], the proof of Theorem 2.9 relies on the auxiliary proposition stated below. We pick a smooth compactification of \( T \) by a simple normal crossing divisor \( j: T \to \overline{T} \) (for example, the projective space), and denote by \( i: \overline{T} - T \to \overline{T} \) the complementary closed immersion. Given any morphism \( \varphi: W \to \overline{T} \) of varieties over \( k \), denote by \( j_W: \varphi^{-1}(T) \to W \) and \( i_W: \varphi^{-1}(\overline{T} - T) \to W \) the corresponding open and closed immersions. Recall the \( \Omega_T \)-sheaf of rank one \( \mathcal{L}_T \) on \( T \) from Section 1.9.

Proposition 2.10. With notation as above, let \( N \) be an object of \( D^b(\varphi^{-1}(T)) \). There exists a finite union \( \mathcal{S} \) of tacs in \( \overline{T} \) such that, for any \( r \geq 0 \) and any \( \xi \in \varphi^{-1}(\overline{T} - T) \), the support of the module \( R^r j_W^* (N \otimes \varphi^* (\mathcal{L}_T))_\xi \) is contained in \( \mathcal{S} \).

Proof. The idea of the proof is to reduce to the situation of [46, Prop. 4.3.1’].

We use induction on the dimension of \( W \). We can then readily assume that \( N \) is a lisse sheaf on a locally-closed irreducible subvariety \( U \) of \( \varphi^{-1}(T) \), extended by zero to \( \varphi^{-1}(T) \). We can assume further that \( U \) is dense in \( W \). Now the monodromy of \( N \) can be assumed to be pro-\( \ell \). Indeed, consider the finite étale cover \( f: U' \to U \) associated to the \( \ell \)-Sylow subgroup of the monodromy group of \( N \), and let \( W' \) be the normalization of \( W \) in the function field of \( U \). The sheaf \( N \) is a direct factor of \( f_* f^* N \), and it suffices to prove the theorem for \( f^* N \) and \( W' \). Hence, we assume that the monodromy of \( N \) is pro-\( \ell \).

By de Jong’s theorem [23, Th. 4.1], there exists an alteration \( f: W' \to W \) such that \( W' \) is smooth and the reduction of the complement of \( f^{-1}(U) \) in \( W' \) is a strict normal crossing divisor. Since we are working over a perfect field, we can further assume that the alteration \( f \) is generically étale. Hence, there exists a dense open subset \( U_0 \) of \( U \) such that \( f \) is finite étale over \( f^{-1}(U_0) \). By induction, it is enough to prove the result for \( U_0 \) and \( N_{|U_0} \), and hence by the same argument as above, it is enough to prove it for \( f_* f^* N_{|U_0} \). By proper base change, it is then enough to prove the result for \( W' \) and \( f^* N_{|U_0} \). By a last dévissage, it is finally enough to prove it for \( f^* N \).

We are now in a situation where we can suppose that \( W \) is smooth, that the complements of \( \varphi^{-1}(T) \) and \( U \) in \( W \) are strict normal crossing divisors, and that the monodromy of \( N \) is pro-\( \ell \). This is exactly the situation at the end of the proof of [46, Prop. 4.3.1’, starting from p. 544, line -4] (with \( N \) replacing \( A \) there) and the remaining argument is identical to that of loc. cit. □

38
Proof. Proof of Theorem 2.9] The fact that Proposition 2.10 implies Theorem 2.9 is completely similar to the fact that Proposition 4.3.1’ implies Théorème 4.1.1’ in [46]. We keep the notation introduced before the statement of Proposition 2.10, and apply Proposition 2.10 with $W = \overline{T}$ and $\varphi$ the identity morphism, so that $j_{W} = j$ and $i_{W} = i$.

Let $\chi \in \overline{T}$ such that $\chi$ does not belong to finite number of tacs of $\overline{T}$ given by Proposition 2.10. Then $i^{*}R_{j_{\ast}}(\mathcal{N}_{\chi}) \in D^{b}_{c}(\overline{T} - T)$ is trivial, and hence its cohomology complex

$$R\Gamma(\overline{T} - T, i^{*}R_{j_{\ast}}(\mathcal{N}_{\chi}))$$

is also trivial. But this last complex is isomorphic to the cone of the morphism

$$R_{s!}(\mathcal{N}_{\chi}) \to R_{s^{\ast}}(\mathcal{N}_{\chi}),$$

where $s: T_{\bar{k}} \to \text{Spec}(\bar{k})$ is the structure morphism, hence the theorem.

We now use Proposition 2.10 to deduce a relative version of Theorem 2.9.

Theorem 2.11. Let $T$ be a torus over $\bar{k}$, let $S$ be an arbitrary scheme over $\bar{k}$, and let $G = S \times T$. Denote by $p: G \to S$ the projection. Let $N \in D^{b}_{c}(G)$.

For $\chi \in \Pi(T)(\overline{\mathcal{Q}_{k}})$ away from a finite union of tacs $\mathcal{I}$, we have $R_{p!}(\mathcal{N}_{\chi}) = R_{p^{\ast}}(\mathcal{N}_{\chi})$.

In particular, if $N$ is a perverse sheaf, then for $\chi$ not in $\mathcal{I}$, the complex $R_{p!}(\mathcal{N}_{\chi}) = R_{p^{\ast}}(\mathcal{N}_{\chi})$ is a perverse sheaf on $S$.

Proof. This is similar to Theorem 2.9. We apply Proposition 2.10 with $W = S \times \bar{k} \times T$, and check that, for each character $\chi$ away from the finite union of tacs given by the proposition, the object $i_{W}^{*}R_{j_{W^{\ast}}}(N \otimes \mathcal{L}_{\chi})$ is trivial, which follows from the immediate extension of [46, Prop. 4.7.2] to an arbitrary base scheme $S$.

Theorem 2.12. Let $T$ be a $d$-dimensional torus over $k$, let $S$ be an arbitrary scheme over $k$, and define $X = T \times S$. Let $i$ be an integer such that $1 \leq i \leq d$.

Let $M$ be a perverse sheaf on $X$. There exist a finite extension $k'$ of $k$ and a family $(S_{f})_{f \in \mathcal{I}}$ of tacs of $T_{k'}$ of dimension $\leq d - i$ with the property that for any $\chi \in \overline{T}_{k'}$ which does not belong to the union of the $S_{f}$ there exists a quotient torus $T_{k'} \to Z$ of dimension $i - 1$ such that

$$R_{q_{\ast}!}(M_{\chi}) = R_{q_{\ast}}(M_{\chi})$$

and this complex is perverse on $B \times k' \times S_{k'}$.

Proof. Up to replacing $k$ by a finite extension, we can assume that $T_{k}$ is split, and thus reduce to $T = \mathbb{G}_{m}^{d}$.

Now let $1 \leq i < d$. For each subset $I$ of $[d] = \{1, \ldots, d\}$ of size $i - 1$, we apply Theorem 2.11 with $(T, S) = (\mathbb{G}_{m}^{[d] \setminus I}, \mathbb{G}_{m}^{I} \times S)$ over $\bar{k}$, so that the projection $p$ in the theorem is then the canonical projection

$$q_{I}: \mathbb{G}_{m}^{d} \times S = \mathbb{G}_{m}^{I} \times S \to \mathbb{G}_{m}^{I} \times S.$$

We obtain a finite union of tacs of $\mathbb{G}_{m}^{[d] \setminus I}$ such that for characters $\chi_{I}$ of $\mathbb{G}_{m}^{[d] \setminus I}$ outside of this finite union, we have

$$R_{q_{\ast}!}(M_{\chi}) = R_{q_{I}}(M_{\chi})$$

and this complex is perverse.

Let

$$(\pi_{I, j}: \mathbb{G}_{m}^{[d] \setminus I} \to Y_{I, j}, \chi_{1, j})_{j \in X_{I}}$$
that there exists some $\chi$ has image of dimension $\leq q$ generated by the $K_i$. In addition, we define $\chi_i,j \in \Pi(G_m^d)(\mathbb{Q}_l)$ to be the character that is trivial on $G^d_i$ and coincides with $\chi_{1,j}$ on $G^d_m$.

Let $\mathcal{F}$ be the set of all maps $f$ from the subsets of $[d]$ of size $i - 1$ to the disjoint union of the $X_i$ that send a subset $I$ to an element $j \in X_i$ for each $I$; this set is finite. For $f \in \mathcal{F}$, let $S_f$ be the intersection of the tacs of $G^d_m$ defined by

$$(G^d_m \to G^d_m/K_{1,f}(1), \chi_{1,f(1)}').$$

We claim that the family $(S_f)_{f \in \mathcal{F}}$ (to be precise, the subfamily where $S_f$ is not empty) satisfies the assertions of the theorem.

Indeed, first of all Lemma 1.25 shows that $S_f$ is either empty or is again a tac; moreover, in the second case, it is defined by the projection $G^d_m \to G^d_m/T_f$ where $T_f$ is the subtorue of $G^d_m$ generated by the $K_{1,f}(1)$ (as subtori of $G^d_m$). By Lemma 1.26 applied to $G_i = G_m$ for all $i$ and the subgroups $K_{1,f}(1)$, we have $\dim(T_f) \geq i$ for all such $f$, and hence the quotient

$$p_f: G^d_m \to Y_f = G^d_m/T_f$$

has image of dimension $\leq d - i$, as desired.

Finally, let $\chi \in \hat{G}^d_m$ be a character that does not belong to any of the tacs $S_f$. This implies that there exists some $f \in \mathcal{F}$, some subset $I \subset [d]$ of size $i - 1$ and some $j \in X_i$ such that the restriction $\chi|_I$ of $\chi$ to $G^d_m$ is not equal to $\chi_{1,i}$.

We can write $\chi = \chi_1 \chi'$ where $\chi'$ is a character of $G^1_m$. Then, considering the quotient $q: G^d_m \to G^1_m$, the base change $q_*$ is the canonical projection $q_1$ and from the application of Theorem 2.11 to $q_1$, we obtain

$$R_{q_1*}(M_\chi) = R_{q_1*}(M_{\chi_1}) \otimes L' = R_{q_1*}(M_{\chi_1}) \otimes L' = R_{q_1*}(M_\chi),$$

and the fact that this object is perverse.

We deduce two corollaries that are sometimes more convenient for applications. The first one is Theorem 2.3 for tori.

**Corollary 2.13.** Let $T$ be a torus of dimension $d$ over $k$. Let $M \in \mathbf{Perv}(T)$. For $-d \leq i \leq d$, the sets

$$\{\chi \in \hat{T} \mid H^i(T_k, M_\chi) \neq 0\}, \quad \{\chi \in \hat{T} \mid H^i_c(T_k, M_\chi) \neq 0\}$$

are contained in a finite union of tacs of $T$ of dimension $\leq d - |i|$, and in particular they have character codimension at least $|i|$.

**Proof.** We apply Theorem 2.12 to $|i|$ and claim that the characters in either of these sets belong to the union of the tacs $S_f$ that arise. Indeed, if $\chi$ is not in any $S_f$, then there exists a quotient torus $T_{k'} \to Z$ of dimension $i - 1$ such that $R_{q_{k'}*}M_\chi = R_{q_{k'}*}M_{\chi'}$ and hence

$$H^i(T_k, M_\chi) = H^i(B_{k'}, R_{q_{k'}*}M_{\chi'}) = 0$$

since $R_{q_{k'}*}M_{\chi'}$ is a perverse sheaf and $\dim(B) = i - 1$. The argument is similar for cohomology with compact support.

**Remark 2.14.** We recall that, concretely, this corollary implies that for $|i| \leq d$, the estimate

$$\left|\{\chi \in \hat{T}(k_n) \mid H^i(T_k, M_\chi) \neq 0 \text{ or } H^i_c(T_k, M_\chi) \neq 0\}\right| \ll |k_n|^{d-|i|}$$

holds for all $n \geq 1$. 40
The following “stratified” statement is also a useful formulation of the result.

**Corollary 2.15.** Let $T$ be a torus of dimension $d$ over $k$ and $S$ a variety over $k$. Set $X = T \times S$ and let $q$ denote the projection $q: X \to S$. Let $M$ be a perverse sheaf on $X$. There exists a finite extension $k'$ of $k$ and a partition of $\tilde{T}_{k'}$ into subsets $(S_i)_{0 \leq i \leq d}$ of character codimension $\geq i$ such that, for any $i$ and $\chi \in S_i$, the object $Rq_!(M_\chi)$ of $D^b_c(S)$ has perverse amplitude $[-i, i]$.

**Proof.** Using the notation of the proof of the theorem, for any integer $i$ with $1 \leq i \leq d$, let $k'_i$ be the finite extension arising from its application to $i$ and let $F_i$ be the corresponding family of tacs. Define $\tilde{S}_i$ to be the union of the $S_f$ for $f \in F_i$ for $1 \leq i \leq d$.

Let $k'$ be the compositum of all $k'_i$. Define $S_0 = \tilde{T} - \tilde{S}_1$ and $S_i = \tilde{S}_i - \tilde{S}_{i+1}$ for $1 \leq i \leq d$. These sets form a partition of $\tilde{T}_{k'}$, and since $S_i \subset \tilde{S}_i$ for $i \geq 1$, they have character codimension $\geq i$. This property is also clear for $i = 0$.

Let $0 \leq i \leq d$, and let $\chi \in S_i$. Then $\chi \notin \tilde{S}_{i+1}$, and hence the theorem provides a projection $q_S: G_{m}^n \times S \to Z \times S$ with $\dim(Z) = i$ such that $Rq_S(M_\chi)$ is perverse. Composing with the projection $Z \times S \to S$ and using Artin’s vanishing theorem, it follows that $Rq_i(M_\chi)$ has perverse amplitude $[-i, i]$. \hfill \Box

**2.4. Perverse sheaves on abelian varieties**

In this section, we will review and extend some results of Krämer and Weissauer on perverse sheaves on abelian varieties.

**2.4.1. Statement of the results and corollaries.** Let $k$ be a finite field, and $\bar{k}$ an algebraic closure of $k$.

Let $X$ be an abelian variety over $k$. We fix a projective embedding $u$ of $X_k$. For subvarieties of $X$, the degree means the degree of the image by $u$; for a tac of $S$ defined by $\pi: X \to A$ and $\chi$, we will say that the degree of $S$ is the degree of the image $u(\ker(\pi))$.

For a perverse sheaf $M$ on $X$, a combination of the main result of Weissauer [113] and of the machinery developed by Krämer and Weissauer [84] implies that for most characters $\chi \in \tilde{X}$, we have $H^i(X_{\bar{k}}, M_\chi) = 0$ for all $i \neq 0$; we will show here that this result can be made quantitative using the complexity of $M$, and will then establish a relative version (see Section 2.4.4).

**Theorem 2.16.** Let $X$ be an abelian variety over $k$. Let $M$ be a perverse sheaf on $X$.

There exist an integer $c \geq 0$ depending only on $c_u(M)$, a finite extension $k'$ of $k$ of degree $\leq c$, and a finite family $(S_f)_{f \in F}$ of tacs of $X_{k'}$ with $|F| \leq c$, each of degree at most $c$, such that any $\chi \in \tilde{X}_{k'}$ which does not belong to the union of the $S_f$ satisfies

$$H^i(X_{\bar{k}}, M_\chi) = 0$$

for all $i \neq 0$.

We will prove this below, but first we establish some corollaries.

**Corollary 2.17.** Let $M \in D^b_c(X)$ be a complex on $X$.

There exist an integer $c \geq 0$, depending only on $c_u(M)$, a finite extension $k'$ of $k$ of degree $\leq c$, and a finite family $(S_f)_{f \in F}$ of tacs of $X_{k'}$, each of degree at most $c$, with $|F| \leq c$, such that for any $\chi \in \tilde{X}_{k'}$ which does not belong to the union of the $S_f$, there is a canonical isomorphism

$$H^i(X_{\bar{k}}, M_\chi) \simeq H^0(X_{\bar{k}}, \mathcal{H}^i(M)_\chi)$$

for all $i \in \mathbb{Z}$.
Proof. This is the same argument as in the proof of Corollary 2.5; the dependency on $c_u(M)$ is obtained by means of Proposition 1.9 to control the perverse cohomology sheaves of $M$. □

Alternatively, the next corollary may be more convenient for applications.

Corollary 2.18. Let $M \in D^b_c(X_k)$ be a complex on $X$. The set $\mathcal{S}$ of characters $\chi \in \hat{X}$ such that we have isomorphisms

$$H^i(X_\bar{k}, M_\chi) \simeq H^0(X_\bar{k}, \mathcal{H}^i(M)_\chi)$$

for all $i \in \mathbb{Z}$ is generic, and the implicit constant in (1.12) depends only on $c_u(M)$.

In particular, if $M$ is a perverse sheaf, then the set of $\chi$ such that $H^i(X_\bar{k}, M_\chi) = 0$ for all $i \neq 0$ is generic and the implicit constant in (1.12) depends only on $c_u(M)$.

Proof. Assume first that $M$ is a perverse sheaf. We apply Theorem 2.16 to $M$, and use the notation there. For $n \geq 1$, let $k_n' = k'k_n$. For any $\chi \in \hat{X}(k_n) - \mathcal{S}(k_n)$, the corresponding character in $\hat{X}(k_n')$ belongs to $S_f(k_n')$ for some $f \in F$. Let $A_f$ be the abelian variety such that $S_f$ is defined by $\pi_f : X_{k'} \to A_f$; we have

$$|\hat{X}(k_n) - \mathcal{S}(k_n)| \leq \sum_{f \in \mathcal{S}} |A_f(k_n')| \leq |\mathcal{S}| (|k'k_n|^1/2 + 1)^{2 \dim(A_f)} \ll |k_n|^\dim(X)-1,$$

where the implied constant depends only on $c_u(M)$ by the theorem.

Now in the general case, recalling that $\mathcal{H}^i(M_\chi)$ is canonically isomorphic to $\mathcal{H}^i(M)_\chi$ for all $i$ and all $\chi$, we have the convergent perverse spectral sequences

$$\mathcal{E}^{i,j}_2 = H^i(X_\bar{k}, \mathcal{H}^j(M)_\chi) \Rightarrow H^{i+j}(X_\bar{k}, M_\chi).$$

By the previous case applied to each of the finitely many perverse cohomology sheaves, the set of $\chi$ such that $H^i(X_\bar{k}, \mathcal{H}^j(M)_\chi) = 0$ for all $i \neq 0$ and all $j$ is generic; for any such character, the spectral sequence degenerates and we obtain isomorphisms

$$H^i(X_\bar{k}, M_\chi) \simeq H^0(X_\bar{k}, \mathcal{H}^i(M)_\chi).$$

Applying Proposition 1.9, we see that the last statement concerning the implicit constant in (1.12) holds. □

Corollary 2.19. Let $X$ be a geometrically simple abelian variety over $k$. Let $M$ be a perverse sheaf on $X$. Then there exists a constant $c$ depending only on $c_u(M)$ and a finite set $\mathcal{S} \subset \Pi(X)(\overline{\mathbb{Q}_l})$ of cardinality at most $c$ such that for $\chi \in \Pi(X)(\overline{\mathbb{Q}_l}) - \mathcal{S}$,

$$H^i(X_\bar{k}, M_\chi) = 0 \text{ for } i \neq 0.$$

Proof. Since $X$ is a geometrically simple abelian variety, then a tac of $X$ contains a single character. Hence, the result follows from Theorem 2.16. □

2.4.2. A rationality lemma. The following is a variant of a result by Bombieri and Zannier [9, Lem. 2].

Lemma 2.20. Let $X$ be an abelian variety over $k$ of dimension $g$, and let $Y$ be a closed subvariety of degree $d$ with respect to some projective embedding $u$ of $X$ of embedding dimension $n$. Let $A \subset X_\bar{k}$ be a non-trivial abelian subvariety such that $A + Y_{\bar{k}} = Y_{\bar{k}}$ which is maximal with this property.

There exists a finite extension $k'$ of $k$, of degree bounded in terms of $(d,g,n)$, such that $A$ is defined over $k'$ and has degree bounded in terms of $(d,g,n)$.
Proof. In this proof, we will say that a closed subvariety $W$ of $X$ has fully bounded degree if it is defined over a finite extension of $k$ of degree bounded in terms of $(d, g, n)$, and if the degree of $u(W)$ is bounded in terms of $(d, g, n)$.

We first observe that since $A$ is non-trivial, we must have $\text{dim}(Y) \geq 1$.

Let $(Y_i)_{i \in I}$ be the family of geometrically irreducible components of $Y$. Note that they are all defined over a finite extension $k'$ of $k$ of degree bounded in terms of $d$. For $a \in A(\bar{k})$ and any $i \in I$, there exists $j \in I$ such that $a + Y_i = Y_j$, so that the group $A(\bar{k})$ acts by permutation on the finite set $\{Y_i\}$. The stabilizer of any fixed irreducible component $Y_i$ is a finite index subgroup of $A(\bar{k})$. But the group $A(\bar{k})$ is divisible since $A$ is an abelian variety, and thus this stabilizer must be equal to $A$. It follows that, $a + Y_i = Y_j$ for any $i \in I$ and any $a \in A(\bar{k})$. Replacing $k$ with $k'$ and $Y$ with one of its geometrically irreducible components, we can therefore assume that $Y$ is irreducible.

We further make a finite extension of $k$ so that $Y(k)$ contains a point $x$; by Lemma 1.12, we can bound the degree of the extension that is required in terms of $(d, g, n)$.

We will now construct inductively a strictly decreasing family

$$Y_0 \supset Y_1 \supset \cdots$$

of irreducible closed subvarieties of dimension $\geq 1$ of $\bar{Y}$, with fully-bounded degree, as follows.

We put $Y_0 = Y_k$. Now suppose that $Y_i$ has been defined for some $i \geq 0$. Let $y \in Y_i(\bar{k})$ be any point different from $x$ (such points exist, since $Y_i$ is of dimension at least 1). Define $V_y = Y_i \cap (x - y + Y_i)$; by the same argument as before, the geometrically irreducible components of $V_y$ are invariant under translation by $A(\bar{k})$. Let $C$ be the set of $y \in Y(\bar{k})$, different from $x$, such that some irreducible component of $V_y$ containing $x$ is a proper subvariety of $Y_i$. The set $C$ is a constructible set, defined over a finite extension of $k$ of degree bounded in terms of $(d, g)$, hence either $C$ is empty, or there exists such a finite extension $k'$ such that $Y(k')$ contains an element of $C$.

In the first case, we define $Y_{i+1}$ to be any irreducible component of $V_y$ containing $x$ with dimension $< \text{dim}(Y_i)$. We have $A + Y_{i+1} = Y_{i+1}$, and (by Bézout’s theorem) the degree of $Y_{i+1}$ is bounded in terms of $d$ and $g$. Thus $Y_{i+1}$ has fully-bounded degree.

In the second case, we end the construction of the sequence.

The second case must arise after at most $g$ steps of the induction; we now define $Z$ to be the last term of the sequence. We thus have $A + Z = Z$, and moreover the fact that the induction cannot be continued beyond $Z$ shows that $(x - z) + Z = Z$ for all $z \in Z(k)$.

The maximality of $A$ among abelian subvarieties with $A + Y = Y$ implies that $A$ is also maximal among abelian subvarieties $B$ of $X$ such that $B + Z = Z$. Let

$$S = \{a \in X \mid a + Z = Z\}.$$  

This is an algebraic subgroup of $X$, and its connected component is an abelian subvariety, and hence is equal to $A$. But for $z \in Z(k)$, we have $A \subset Z - z$ as well as $z - Z \subset S$, and hence $A = Z - z$ since the latter is irreducible. The construction of the subvariety $Z$ therefore shows that $A$ is of fully bounded degree, which concludes the proof. \qed

2.4.3. Conclusion of the proof. We now proceed with the proof of Theorem 2.16. As we indicated, the first ingredient is a quantitative version of a result of Weissauer [113],

Proposition 2.21. Let $X$ be an abelian variety over $k$ with a projective embedding $u$, and let $M$ be a geometrically simple perverse sheaf on $X$ such that $\chi(X_\bar{k}, M) = 0$.  

43
There exists a finite extension $k'$ of $k$ of degree bounded in terms of $c_u(M)$ and a tac $S$ on $X_{k'}$ with kernel an abelian subvariety $A_{k'}$ of degree bounded in terms of $c_u(M)$, such that

$$\bigoplus_i H^i(X_{k'}, M_{\chi}) \neq 0$$

if and only if $\chi$ is in $S$.

**Proof.** By [113, Th. 3 and Lem. 6], there exists a maximal abelian variety $A_{\bar{k}}$ of $X_{\bar{k}}$ such that $M$ is invariant by translation by $A_{\bar{k}}$, and this abelian variety is non-trivial.

Denoting by $q: X_{\bar{k}} \to X_{\bar{k}}/A_{\bar{k}}$ the quotient morphism, this is equivalent to the fact that $M$ is isomorphic over $\bar{k}$ to a perverse sheaf of the form $\mathcal{L}_{\chi_0} \otimes q^*(\tilde{M})[\dim(A)]$ for some character $\chi_0: \pi_1(X_{\bar{k}}) \to \mathcal{Q}$ and some simple perverse sheaf $\tilde{M}$ on $X_{\bar{k}}/A_{\bar{k}}$. The first step is now to prove that $A_{\bar{k}}$ and $M$ are defined over a finite extension of $k$ of degree bounded in terms of $c_u(M)$, and that the degree of $A_{\bar{k}}$ in the image of $u$ is similarly bounded.

Let $k' \supset k$ be the field of definition of $A_{\bar{k}}$; it is a finite extension of $k$. Let $Z \subset X$ be the support of $M$, which is a closed subvariety of $X$, and let $U \subset Z$ be the maximal open subset on which $M$ is lisse, and $Y = Z - U$. By Theorem 1.7, the degrees of $Z_{\bar{k}}$ and $Y_{\bar{k}}$ are bounded in terms of $c_u(M)$.

Since $M$ over $\bar{k}$ is invariant by translation by closed points of $A_{\bar{k}}$, the same holds for $Z$ and $U$, and hence also for $Y$, so that $A_{\bar{k}} + Y_{\bar{k}} = Y_{\bar{k}}$. By Lemma 2.20, the abelian variety $A_{\bar{k}}$ is defined over a finite extension of $k$ of degree bounded in terms of the degree of $Y$, and hence of $c_u(M)$, and with degree in the image of $u$ also bounded. This concludes the proof of the claim.

Now let $\chi$ be a character not in the tac of $X_{k'}$ defined by $(q, \chi_0^{-1})$. We now compute for every $i \in \mathbb{Z}$ that

$$H^i(X_{\bar{k}}, M_{\chi}) = H^i((X/A)_{\bar{k}}, Rq_* (M_{\chi})) = H^i((X/A)_{\bar{k}}, Rq_* (\mathcal{L}_{\chi_0} \otimes \tilde{M}[[\dim(A)]).$$

Since $\chi$ is not in the tac $S$, the restriction of $\mathcal{L}_{\chi_0}$ to $A_{\bar{k}}$ is non-trivial, and hence we have $Rq_* (\mathcal{L}_{\chi_0}) = 0$ by Lemma 1.16, and therefore $H^i(X_{\bar{k}}, M_{\chi}) = 0$ for all $i$.

Conversely, if $\chi = \chi_0^{-1} \cdot (\chi \circ q)$, then we have

$$H^*(X_{\bar{k}}, M_{\chi}) = H^*(A_{\bar{k}}, \mathcal{Q}_{\bar{k}}) \otimes H^*((X/A)_{\bar{k}}, \tilde{M}_{\bar{k}}[[\dim(A)]],$$

by the Künneth formula, and this is non-zero since $A$ was maximal such that $M$ is geometrically invariant by translation by $A$, so that the Euler–Poincaré characteristic of the perverse sheaf $\tilde{M}$ is non-zero.

**Remark 2.22.** With some extra work, one can prove that one can choose the character $\chi_0$ defining the tac of Proposition 2.21 to be of finite order, i.e., to belongs to $(\bar{X}/A)_{k'}$.

**Proof of Theorem 2.16.** We follow the method used by Krämer and Weissauer to prove [84, Th. 1.1], keeping track of the complexity.

Since $X$ is an abelian variety, the two convolution products of Section 1.4 coincide; for an object $M$ of $\mathcal{D}^b_c(X)$ and an integer $n \geq 1$, we denote by $M^{*n}$ the $n$-th iterated convolution product of $M$.

We recall the axiomatic framework of [84, Section 5], specialized to our situation as in [84, Example 5.1]. Let $D$ be the full subcategory of $\mathcal{D}^b_c(X_{\bar{k}})$ whose objects are direct sums of shifts of geometrically semisimple perverse sheaves which are obtained by pullback from $X_{k_n}$ for some $n \geq 1$. Let $P \subset \mathbf{Perv}(X_{\bar{k}})$ be the corresponding subcategory of perverse sheaves, namely that with objects the geometrically semisimple perverse sheaves arising by pullback from $X_{k_n}$ for some $n \geq 1$. Then the categories $P$ and $D$ satisfy the axioms (D1), (D2), and (D3) of [84, Section 5], namely:
(D1) The category $D$ is stable under degree shift, convolution and perverse truncation functors; the category $P$ is the heart of this $t$-structure, and is a semisimple abelian category.

(D2) Any object $M$ of $D$ can be written (non-canonically) as a direct sum

$$\bigoplus_{n \in \mathbb{Z}} \mathcal{H}^n(M)[-m].$$

(D3) The Hard Lefschetz Theorem holds for objects of $D$.

Let $N$ be the full subcategory of $D$ whose objects are the complexes $N$ such that all geometrically simple constituents of all perverse cohomology sheaves $\mathcal{H}^i(N)$ for $i \in \mathbb{Z}$ have Euler–Poincaré characteristic equal to 0. By [84, Cor. 6.4], the category $N$ satisfies the axioms (N1), (N2), (N3) and (N4) of [84, Section 5], namely:

(N1) We have $N \ast D \subset N$ and the category $N$ is stable under direct sums, retracts, degree shifts, perverse truncation and duality;

(N2) If $N$ is an object of $N$, then for most characters $\chi$, we have $H^i(X, N_\chi) = 0$ for all $i$;

(N3) The category $N$ contains all objects $M$ of $D$ such that $H^i(X, N) = 0$ for all $i \in \mathbb{Z}$;

(N4) The category $N$ contains all simple objects of $P$ with zero Euler–Poincaré characteristic.

(Note that we will not make use of this version of (N2).)

By [84, Theorem 9.1], every $M \in P$ is a $N$-multiplier, meaning that for all integers $i \neq 0$ and any integer $r \geq 1$, every subquotient of $\mathcal{H}^i((M \oplus M^r)^*)$ lies in $N$.

We now argue as in the proof of [84, Lemma 8.2] to prove Theorem 2.16 for a perverse sheaf $M$ on $X$.

**Step 1.** We assume that $M$ is arithmetically simple. By Lemma 1.28, the base change of $M$ to $\bar{k}$ is an object of $P$. We denote $g = \dim(X)$; by (D2), we have

$$M_k^{g+1} \cong \bigoplus_{m \in \mathbb{Z}} M_m[m],$$

for some objects $M_m$ of $P$, which are in fact objects of $N$ for $m \neq 0$ since $M$ is an $N$-multiplier.

By Proposition 1.9, the number of integers $m$ such that $M_m$ is non-zero is bounded in terms of $c_u(M)$, and similarly $c_u(M_m)$ is bounded in terms of $c_u(M)$. By the semisimplicity property in (D1), each $M_m$ is a direct sum of simple perverse sheaves in $N$, and by Proposition 1.9, the number and the complexity of these constituents are bounded in terms of $c_u(M)$. We denote by $\mathcal{C}$ the finite set of all these simple perverse sheaves. By Lemma 1.28, there exists a finite extension $k'$ of $k$, of degree bounded in terms of $c_u(M)$, such that any element $C$ of $\mathcal{C}$ is defined over $k'$.

We apply Proposition 2.21 to each $C \in \mathcal{C}$. Let $\mathcal{S}_C$ denote the corresponding tac; it is of degree bounded in terms of $c_u(M)$.

We claim that if $\chi \notin \hat{\mathcal{X}}$ does not belong to the union of the tacs $\mathcal{S}_C$, then we have

$$H^i(X, M_\chi) = 0$$

for all $i \neq 0$. This statement will conclude the proof of Theorem 2.16 for $M$.

Let $\chi$ be a character that is not in any of the tacs $\mathcal{S}_C$. Since $M_\chi^{g+1}$ is isomorphic to $(M^{g+1})_\chi$ and $H^*(X, C_\chi) = 0$ for $\chi \notin \mathcal{S}_C$, we have

$$H^i(X, M_\chi^{g+1}) = H_i(X, M_0\chi),$$

for any $i \in \mathbb{Z}$. The right-hand side vanishes if $|n| > g$ since $M_0$ is perverse. Finally, by the compatibility between convolution and the Künneth formula (see Lemma 1.15 below) we also have
an isomorphism
\[ H^\bullet(X^*_{\bar{k}}, M^*_{\chi}^{(g+1)}) \simeq H^\bullet(X^*_{\bar{k}}, M_{\chi})^{(g+1)}, \]
and by comparing we see that only the space \( H^0(X^*_{\bar{k}}, M_{\chi}) \) may be non-zero, which establishes the claim.

**Step 2.** Now let \( M \) be an arbitrary perverse sheaf on \( X \). By Proposition 1.9, the number of geometric Jordan–Hölder factors of \( M \) is bounded in terms of \( c_u(M) \), and hence also the number of arithmetic Jordan-Hölder factors; we then apply the first step to each of the terms of a composition series for \( M \), and deduce the corresponding result for \( M \).

\[ \square \]

2.4.4. The relative version. Our next goal is to establish a relative version of Theorem 2.16. The arguments of Krämer and Weissauer in [84, Section 2] when the base field is \( \mathbb{C} \) do not apply, since they rely on Verdier stratifications. We instead use a constructibility result of Orgogozo [97], which is a stratification result, locally for the alteration topology.

**Theorem 2.23.** Let \( S \) be a quasi-projective scheme over \( k \), and let \( A \) be an abelian variety over \( k \). Let \( X = A \times S \), and denote by \( f : X \to S \) the canonical morphism. Fix a projective embedding \( u \) of \( X \).

Let \( \alpha : X' \to X \) be an alteration defined over \( k \), and \( \mathcal{Z}' \) a stratification of \( X' \).

Let \( a \leq b \) be integers. Let \( M \) be an object of \( D^b_c(X) \) with perverse amplitude \([a, b]\) such that \( \alpha^* M \) is tame and constructible along \( \mathcal{Z}' \).

There exist an integer \( d \geq 1 \), a finite extension \( k' \) of \( k \) and a finite family \( (S_f)_{f \in \mathcal{F}} \) of tacs of \( \tilde{A}_{k'} \), such that

1. The integer \( d \) and the size of \( \mathcal{F} \) are bounded in terms of \( c_u(M) \) and the data \((X, X', \alpha, \mathcal{Z}')\),
2. Each tac \( S_f \) has degree at most \( d \),
3. The degree of \( k' \) is at most \( d \),

with the property that for any \( \chi \in \tilde{A}_{k'} \) which does not belong to the union of the \( S_f \), the object \( Rf_*(M_{\chi}) \) has perverse amplitude \([a, b]\).

By [97, Prop.1.6.7], for any object \( M \) of \( D^b_c(X) \), there does exist an alteration \( \alpha : X' \to X \) (in fact, a finite surjective morphism) and a stratification \( \mathcal{Z}' \) of \( X' \) such that \( \alpha^* M \) is tame and constructible along \( \mathcal{Z}' \). In particular, the following corollary follows.

**Corollary 2.24.** Let \( S \) be a quasi-projective scheme over \( k \) and let \( A \) be an abelian variety over \( k \). Define \( X = A \times S \) and denote \( f : A \times S \to S \) the projection.

Let \( a \leq b \) be integers and let \( M \) be an object of \( D^b_c(X) \) with perverse amplitude \([a, b]\). There exist a finite extension \( k' \) of \( k \) and a finite family \( (S_f)_{f \in \mathcal{F}} \) of tacs of \( \tilde{A}_{k'} \) such that for any character \( \chi \in \tilde{A}_{k'} \) that does not belong to the union of the \( S_f \), the object \( Rf_*(M_{\chi}) \) has perverse amplitude \([a, b]\).

For the proof of Theorem 2.23, we use the following special case of [97, Th. 3.1.1].

**Theorem 2.25 (Orgogozo).** Let \( f : X \to Y \) be a proper morphism defined over \( k \). Let \( \alpha : X' \to X \) be an alteration and \( \mathcal{Z}' \) a stratification of \( X' \). Then there exist an alteration \( \beta : Y' \to Y \) and a stratification \( \mathcal{Z}' \) of \( Y' \) such that for any object \( M \) of \( D^b_c(X) \), the condition that \( \alpha^*(M) \) is tame and constructible along \( \mathcal{Z}' \) implies that \( \beta^* Rf_*(M) \) is tame and constructible along \( \mathcal{Z}' \).

**Proof of Theorem 2.23.** By shifting and Verdier duality, it is enough to prove the weaker statement where “\( M \) is of perverse amplitude \([a, b]\)” is replaced by “\( M \) is semiperverse”.

Apply Theorem 2.25 to the proper morphism \( f : A \times S \to S \) and to the alteration \( \alpha \). We obtain an alteration \( \beta : S' \to S \) and a stratification \( \mathcal{Z}' \) of \( S' \) such that \( \beta^* Rf_*(M) \) is tame and constructible
along $\mathcal{S}'$. Note that since any $\mathcal{L}_\chi$ is lisse and tame, $\alpha^* M_\chi$ is tame and constructible along $\mathcal{X}'$ (see [97, 5.2.5] for details), and hence the complex $\beta^* Rf_* M_\chi$ is also tame and constructible along $\mathcal{S}'$ for any $\chi \in \hat{\mathbb{A}}$.

Consider the image of the stratification $\mathcal{S}'$ by $\beta$. By Chevalley’s theorem, it is covering of $\mathbb{S}$ by constructible sets, but not necessarily a partition. Refine this covering and remove redundant strats in order to obtain a stratification $\mathcal{S}$ of $\mathbb{S}$ where all strats are equidimensional. Then refine the stratification $\mathcal{S}'$ in such a way that preimages by $\beta$ of strats of $\mathcal{S}$ are union of strats of $\mathcal{S}'$ and that $\beta$ induces surjective morphisms from each strat of $\mathcal{S}'$ to a strat of $\mathcal{S}$.

Let $\chi \in \hat{\mathbb{A}}$. Even if the complex $Rf_* M_\chi$ is not necessarily constructible along $\mathcal{S}$, it has the property that for any strat $S_i$ of $\mathcal{S}$, the support of the restriction of each cohomology sheaf of $Rf_* M_\chi$ to $S_i$ is either $S_i$ or empty, since the analogue property holds for $\beta^* Rf_* M_\chi$ and the stratification $\mathcal{S}'$, and $\beta$ is surjective from a strat of $\mathcal{S}'$ to one of $\mathcal{S}$.

Consider now the preimage of the stratification $\mathcal{S}$ by $f$, and also the image of the stratification $\mathcal{S}'$ of $X'$ by $\alpha$. Choose a stratification $\mathcal{X}$ of $X$ that refines both these coverings of $X$, with the property that for any strats $X_i$ and $S_j$ of $\mathcal{X}$ and $\mathcal{S}$ such that $f(X_i) \subset S_j$, the restriction of $f$ to $X_i$ is smooth (in particular, that $X_i$ is equidimensional above $S_j$). Now refine $\mathcal{X}'$ similarly to $\mathcal{S}'$, in such a way that preimages by $\alpha$ of strats of $\mathcal{X}$ are union of strats of $\mathcal{S}'$ and $\alpha$ induces surjective morphisms from any strat of $\mathcal{X}'$ to a strat of $\mathcal{X}$.

By Lemma 1.12, up to replacing $k$ with a finite extension of degree bounded in terms of $c_u(M)$ (and the fixed data $(X, X', \alpha, \mathcal{X}')$), we can assume that each strat $S_i$ of $\mathcal{S}$ has a $k$-rational point $s_i$. We now apply Corollary 2.17 for each $i$ to the restriction $M_{s_i}$ of $M$ to $f^{-1}(s_i) \simeq \mathbb{A}$ for each $i$, obtaining extensions $k_i$ of $k$ and families $(S_{f,i})_{f \in \mathcal{S}_i}$ of tacs of $\hat{\mathbb{A}}_{k_i}$ satisfying the properties of this corollary.

Let $k'$ be the compositum of all $k_i$, which has degree bounded in terms of $c_u(M)$ and the fixed data. We claim that for any character $\chi \in \hat{\mathbb{A}}_{k'}$ that belongs to none of the tacs $S_{f,i}$ for any $i$, the object $Rf_* M_\chi$ is semiperverse. This will conclude the proof.

Suppose that the claim fails for some $\chi$. Then there exists an integer $k \in \mathbb{Z}$ such that
\[
\dim \text{Supp}(\mathcal{H}^k(Rf_* (M_\chi))) > -k.
\]
Since $\text{Supp}(\mathcal{H}^k(Rf_* (M_\chi)))$ is a union of strats of $\mathcal{S}$, there is a strat $S_i \subset \text{Supp}(\mathcal{H}^k(Rf_* (M_\chi)))$ of $\mathcal{S}$ of dimension $> -k$. In particular, we have $\mathcal{H}^k(Rf_* (M_\chi))_{s_i} \neq 0$. By proper base change, we have $\mathcal{H}^k(Rf_* (M_\chi))_{s_i} = H^k(A_{k} \times \{ s_i \}, M_{s_i \chi})$, and hence the latter is also non-zero. From the assumption on $\chi$ and Corollary 2.17, we have
\[
H^k(A_{k} \times \{ s_i \}, M_{s_i \chi}) \simeq H^0(A_{k} \times \{ s_i \}, \mathcal{H}^k(M_{s_i})_\chi),
\]
and hence $\mathcal{H}^k(M_{s_i}) = \mathcal{H}^0(M_{s_i}[-k]) \neq 0$. By definition of the perverse t-structure, this implies that there exists some $r \in \mathbb{Z}$ such that
\[
\dim \text{Supp}(\mathcal{H}^r(M_{s_i})) = -r + k \geq 0.
\]

The support of $\mathcal{H}^r(M)$ is a union of strats of $\mathcal{X}$, so there exists a strat $X_j \subset \text{Supp}(\mathcal{H}^r(M))$ of $\mathcal{X}$ with $\dim(X_j \cap A \times \{ s_i \}) = -r + k$. Since $X_j$ is equidimensional over $S_i$ and $\dim(S_i) > -k$, we conclude that
\[
\dim \text{Supp}(\mathcal{H}^r(M)) \geq \dim(X_j) = -r + k + \dim(S_i) > -r,
\]
contradicting the semiperseverence of $M$. □

We now prove a vanishing theorem for higher cohomology groups of perverse sheaves on abelian varieties. We begin with an analogue of Theorem 2.12.
Proposition 2.26. Let A be a g-dimensional algebraic variety over k, let S be a quasi-projective scheme over k, and define X = A × S. Fix a projective embedding u of X.

Let α: X’ → X be an alteration and x’ a stratification of X’.

Let i be an integer with 1 ≤ i ≤ g. Let a ≤ b be integers.

Let M be an object of $D_\mathbf{c}(X)$ with perverse amplitude $[a, b]$ such that $\alpha^*M$ is tame and constructible along $x’$. There exist a finite extension $k’$ of k and a family $(S_f)_{f \in \mathcal{F}}$ of tacs of $A_{k’}$ of dimension $\leq d - i$ with the property that for any $\chi \in \hat{A}_{k’}$ which does not belong to the union of the $S_f$ there exists a quotient abelian variety $q: A_{k’} \to B$ of dimension at most $i - 1$ such that $R_qS_{\alpha,M,\chi}$ has perverse amplitude $[a, b]$.

Moreover, the degree of $k’$ over k and the size of $\mathcal{F}$ depend only on $c_u(M)$ and $(X, X’, \alpha, x’)$.

Proof. As in the proof of Theorem 2.25, we can work with each perverse cohomology sheaf, and it is therefore enough to prove the proposition for $a = b = 0$, which means that M is perverse.

By Poincaré’s complete reducibility theorem, up to replacing k with a finite extension, there exists an isogeny $f: A \to B$ over k where B is a product of geometrically simple abelian varieties. We first claim that it is enough to prove the proposition for B.

To see this, we assume that the statement holds for B. Consider the base change $f_B: X \to B \times S$. Since f is finite, $f_*\pi_*M$ is perverse for every perverse sheaf M on A. By Theorem 2.25, we find an alteration $\beta: B' \to B \times S$ and a stratification of B’ such that $\beta^*f_*\pi_*M_{\chi}$ is tame and adapted for every M such that $\alpha^*M$ is tame and adapted to $x’$. Then the proposition can be applied to $f_*\pi_*M_{\chi}$. Let N be the kernel of the isogeny f. Choose up to $|N|$ characters of A whose restrictions to N run over the character group of N. Then the proposition for A follows by applying the result for B to the objects $f_*\pi_*M_{\chi}$, where $\chi$ varies among this finite set of characters. This proves the claim.

So we assume that $A = A_1 \times \cdots \times A_s$ is a product of geometrically simple abelian varieties. Set $g_j = \dim(A_j)$ for all j. For any subset $I \subset [s]$, let

$$A_I = \prod_{i \in I} A_i,$$

viewed as a subvariety of A, and let $A_i^\perp = A_{[s]-I}$ be the kernel of the canonical projection $A \to A_I$.

Fix an integer $1 \leq i \leq g = \dim(A)$. Let $\mathcal{E}$ be the set of subsets $I \subset [s]$ such that $\dim(A_I) < i$; for $I \in \mathcal{E}$, we have $\dim(A_I^\perp) > g - i$.

Fix $I \in \mathcal{E}$. Let $p: A \times S \to A_I \times S$ be the projection. We apply Theorem 2.23 to p and M, i.e., with $(A, S)$ there equal to $(A_I^\perp, A \times S)$. Up to replacing k by a finite extension $k'$, we obtain a finite family $(S_{I,j})_{j \in X_I}$ of tacs of $A_{I,k'}$ such that the object $R_p\pi_*M_{\chi}$ is perverse on $A_I \times S$ for any $\chi \in \hat{A}_{I,k'}$ not in the union of these tacs. Let

$$(\pi_{I,j}, \chi_{I,j})_{j \in X_I}$$

be the projection and characters defining these tacs, and let $K_{I,j} = \ker(\pi_{I,j})$, viewed as a subgroup of $A_{k'}$.

Let $\mathcal{F}$ be the set of all maps $f$ from $\mathcal{E}$ to the disjoint union of the $\mathcal{J}_I$ that send a subset I to an element $j \in X_I$ for each I; this set is finite. For $f \in \mathcal{F}$, let $S_f$ be the intersection of the tacs of $A_{k'}$ defined by

$$(A_{k'} \to A_{k',K_{I,f(I)},\chi_{I,f(I)}})$$

for $I \in \mathcal{E}$.
We claim that the family $(S_f)_{f \in \mathcal{F}}$ (to be precise, the subfamily where $S_f$ is not empty) satisfies the assertions of the theorem.

Indeed, first of all Lemma 1.25 shows that $S_f$ is either empty or is again a tac; moreover, in the second case, it is defined by the projection $A_{k'} \to A_{k'}/B_f$ where $B_f$ is the abelian subvariety in $A_{k'}$ generated by the $K_{1,f}(I)$, viewed as subvarieties of $A_{k'}$. For such $f$, by Lemma 1.26 applied to $A$ and the subgroups $K_{1,f}(I)$, we have $\dim(B_f) \geq i$, and hence the quotient

$$p_f: A_{k'} \to A_{k'}/B_f$$

has image of dimension $\leq d - i$.

Finally, let $\chi \in \hat{A}_{k'}$ be a character that does not belong to any of the tacs $S_f$. This implies that there exists some $f \in \mathcal{F}$, some subset $I \subset \mathcal{F}$ and some $j \in X_I$ such that the restriction $\chi_I$ of $\chi$ to $A^1_{I,k'}$ is not equal to $\chi_{1,j}$.

We can write $\chi = \chi'_1 \chi'$ where $\chi'$ is a character of $A_{1,k'}$. Then, considering the particular quotient $q: A_{k'} \to A_{1,k'}$, the base change $q_{S}$ is the canonical projection $q_{1}$ and hence

$$Rq_{S*}M_{\chi} = Rq_{S}(M_{\chi_1}) \otimes L_{\chi'}$$

is perverse. \hfill \Box

As in the case of tori, we state two further consequences that are useful in applications.

**Corollary 2.27.** Let $A$ be an abelian variety defined over $k$ of dimension $g$. Let $M$ be a perverse sheaf on $A$. For $-g \leq i \leq g$, the sets

$$\{ \chi \in \hat{A} \mid H^i(A, M_\chi) \neq 0 \}$$

are contained in a finite union of tacs of $A$ of dimension $\leq g - \vert i \vert$, and in particular they have character codimension at least $\vert i \vert$.

**Proof.** We argue as in the proof of Corollary 2.13 using the previous theorem (with $a = b = 0$), as we may since we have recalled that one can find an alteration $\alpha$ of $A$ such that the pull-back $\alpha^*M$ is tame. \hfill \Box

**Corollary 2.28.** Let $A$ be a $g$-dimensional algebraic variety over $k$, let $S$ be a quasi-projective scheme over $k$, and define $X = A \times S$. Fix a projective embedding $u$ of $X$.

Let $\alpha: X' \to X$ be an alteration and $\mathcal{X}'$ a stratification of $X'$.

Let $M$ be a perverse sheaf on $X$ such that $\alpha^*M$ is tame and constructible along $\mathcal{X}'$. There exists a finite extension $k'/k$ and a partition of $\hat{A}_{k'}$ into subsets $(S_i)_{0 \leq i \leq g}$ of character codimension $\geq i$ such that for any $i$ and $\chi \in S_i$, the object $Rq_{0*}M_{\chi}$ has perverse amplitude $[-i, i]$.

Moreover, for any integer $n \geq 1$, we have

$$|S_i(k_n)| \ll |k|^{|n(g-i)|},$$

where the implied constant depends only on $(c_u(M), X, X', \alpha, \mathcal{X}')$.

**Proof.** We argue as in the proof of Corollary 2.15 for the first part; to deduce (2.5), we simply note for each $i \leq g$, the number of tacs in Proposition 2.26 is bounded in terms of the indicated data, and for each tac $S$ of dimension $i$, the number of characters in $S(k_n)$ is $\leq (|k_n|^{1/2} + 1)^{2i} \ll |k|^{ni}$. \hfill \Box
2.5. Proof of the general vanishing theorem

We can now prove Theorem 2.3.

We consider the dévissage of Proposition 1.13. Namely, let $A$ be an abelian variety, $T$ a torus, $U$ a unipotent group and $N$ a finite commutative subgroup scheme of $A \times U \times T$ such that $G$ is isomorphic to $(A \times U \times T)/N$. Further, we write $N = N_r \times N_l$ where $N_r$ is reduced and $N_l$ is local.

Let $M$ be a perverse sheaf on $G$.

**Step 1.** We claim that it is enough to prove the theorem for the group $\tilde{G} = A \times U \times T$.

Indeed, since $N = N_r \times N_l$, the quotient morphism $p: \tilde{G} \to G$ can be factored as the composition of an étale isogeny and a purely inseparable one. The latter is a universal homeomorphism, and since universal homeomorphisms preserve the étale site, and since pull-back by a finite étale map preserves perversity, it follows that the pull-back $p^*(M)$ is perverse.

Assume that the result of Theorem 2.3 holds for $p^*(M)$ on $\tilde{G}$. Then we obtain the vanishing theorem for $M$ as follows. Let $\mathcal{J}'$ be the subsets of loc. cit. for $p^*(M)$ on $\tilde{G}$, and define $\mathcal{J}_i$ to be the set of $\chi \in \tilde{G}$ such that $p \circ \chi \in \mathcal{J}'$. Since $G$ has the same dimension as $\tilde{G}$ and $\mathcal{J}'$ has character codimension $i$, do does $\mathcal{J}_i$.

If $\chi \in \tilde{G}$, then the projection formula gives isomorphisms

$$H^i(\tilde{G}, p^*(M_\chi)) = H^i(\tilde{G}, p^*(M)_{\chi \circ p})$$

for all $i \in \mathbb{Z}$.

The vanishing of $H^i(\tilde{G}, p^*(M_\chi))_{\chi \circ p}$ implies that of $H^i(G_k, M_\chi)$, since the latter space is a direct summand of the former. A similar argument applies for compactly-supported cohomology, which shows that the characters $\chi \in \tilde{G}$ such that any of the groups (2.2) is non-zero belong to $\mathcal{J}_i$.

Finally, suppose that $\chi \in \mathcal{J}_0 - \mathcal{J}_1$, so that $p \circ \chi \in \mathcal{J}_0' - \mathcal{J}_1'$. Since the forget support map is functorial, the forget support morphism

$$H^0_c(\tilde{G}_k, p^*(M_\chi)) \to H^0(\tilde{G}_k, p^*(M_\chi))$$

induces by restriction the forget support morphism

$$H^0_c(G_k, M_\chi) \to H^0(G_k, M_\chi),$$

and since the former is an isomorphism (from our assumption that Theorem 2.3 holds for $\tilde{G}$), so is the latter. This concludes the proof of the claim of Step 1.

**Step 2.** We now assume that $G = A \times U \times T$. We fix a quasi-projective immersion $u$ of $G$. Let $d_A = \dim(A)$, $d_U = \dim(U)$, $d_T = \dim(T)$, and $d = d_A + d_U + d_T = \dim(G)$.

Up to replacing $k$ by a finite extension, we can assume that $T$ is split. By applying Corollary 2.15 with $S = A \times U$, we can partition $\tilde{T}$ into subsets $(S_i)_{0 \leq i \leq d_T}$ of character codimension $\geq i$ such that if $\chi \in S_i$, then the complex $R\pi(M_\chi) \in D^b(A \times U)$ is of perverse amplitude $[-i, i]$, where $p: A \times U \times T \to A \times U$ is the canonical projection.

We now wish to apply Proposition 2.26 to $A \times U$, but we first need to find an alteration that moderates all complexes $R\pi(M_\chi)$.

Let $j: T \to \bar{T} = (\mathbb{P}^1)^{d_T}$ be the obvious compactification of $T$. By [97, Prop. 1.6.7], there exists an alteration $\alpha: X \to A \times U \times \bar{T}$ and a stratification $\mathcal{S}$ of $X$ such that $\alpha^*(j_!M)$ is tame and constructible along $\mathcal{S}$. For each character $\chi \in \bar{T}$, the sheaf $j_!(\mathcal{L}_\chi)$ is tame, and hence $\alpha^*(j_!M_\chi)$ is also constructible and tame along $\mathcal{S}$ (see [97, 5.2.5] for details).
We apply Theorem 2.25 to the proper projection $A \times U \times \hat{T} \to A \times U$. This provides us with an alteration $\beta: X' \to A \times U$ and a stratification $\mathcal{X}'$ of $X'$ such that the complex $\beta^*R\pi_{T!}(M_\chi)$ is tame and constructible along $\mathcal{X}'$ for every $\chi \in \hat{T}$. Moreover, by Proposition 1.18 and Theorem 1.5, the complexity of $R\pi_{T!}(M_\chi)$ is bounded independently of $\chi \in \hat{T}$.

We can now apply Corollary 2.28 to $S = U$ and the complexes $R\pi_{T!}(M_\chi)$. For each character $\chi \in \hat{T}$, we obtain a partition $(S_{\chi,j})_{0 \leq j \leq d_\chi}$ of $\hat{A}$ into subsets such that $S_{\chi,j}$ has character codimension at least $j$, with the property that for $(\chi, \xi) \in S_i \times S_{\chi,j}$, the complex $R\pi_A!(R\pi_{T!}(M_\chi))_\xi$ has perverse amplitude $[-i - j, i + j]$.

By Proposition 1.18 and Theorem 1.5, the complexity of the object $R\pi_A!(R\pi_{T!}(M_\chi))_\xi$ is bounded independently of $(\chi, \xi) \in S_i \times S_{\chi,j}$. Hence, by applying Proposition 2.7 to these objects we find for each $(\chi, \xi)$ a partition $(S_{\chi,\xi,m})_{0 \leq m \leq d_U}$ of $\hat{U}$ such that the set $S_{\chi,\xi,m}$ has character codimension at least $m$ and, moreover, we have

$$H^\omega_c(G_k, M_{\chi,\xi}) = 0$$

for each $\psi \in S_{\chi,\xi,m}$ unless $n \in [-i - j, i + j + m]$.

For $0 \leq r \leq d$, we now define $\tilde{\mathcal{F}}_r$ to be the set of characters $(\chi, \xi, \psi) \in \hat{G}$ such that

$$\psi \in S_{\chi,\xi,m}, \quad \xi \in S_{\chi,j}, \quad \chi \in S_i$$

for some $i, j, m$ such that $i + j + m \geq r$.

For any integer $n \geq 1$, we have

$$|\tilde{\mathcal{F}}_r(k_n)| = \sum_{i+j+m \geq r} \sum_{\chi \in S_i(k_n)} \sum_{\xi \in S_{\chi,j}(k_n)} |S_{\chi,\xi,m}(k_n)| \ll |k|^{n(d-(i+j+m)} \ll |k|^{n(d-r)}$$

by (2.4) and (2.5) (note that the uniformity with respect to the perverse sheaf in these estimates, and the uniform bound on the complexity, are crucial to control the sums over $\chi$ and $\xi$). Thus the set $\tilde{\mathcal{F}}_r$ has character codimension at least $r$.

By construction of the sets $S_i$, $S_{\chi,j}$ and $S_{\chi,\xi,m}$, the condition $H^\omega_c(G_k, M_{\chi,\xi}) \neq 0$, for $(\chi, \xi, \psi) \in \hat{G}$, implies that $(\chi, \xi, \psi) \in \mathcal{F}_{|\xi|}$. We apply a similar argument with $D(M)$ to obtain the analogue conclusion for ordinary cohomology and set $\mathcal{F}_i$ to be the intersection of the set $\tilde{\mathcal{F}}_r$ for $M$ and of the analogue for $D(M)$. By construction, the sets $\mathcal{F}_i$ satisfy the first two claims of Theorem 2.3.

We now establish the last claims of Theorem 2.3.

First, let $(\chi, \xi, \psi) \in \hat{G} \in \mathcal{F}_i$. By Theorem 2.12, we have $R\pi_{T!}(M_\chi) = R\pi_{T*}(M_\chi)$. Moreover $p_A! = p_A*$ since $p_A$ is proper, and by the last claim of Proposition 2.7, we obtain

$$H^0(G_k, M_{\chi,\xi}) = H^0(U_k, R\pi_A! R\pi_{T*} M_{\chi,\xi}) = H^0_c(U_k, R\pi_A! R\pi_{T!} M_{\chi,\xi}) = H^0_c(G_k, M_{\chi,\xi}).$$

Finally, if $G$ is a torus (resp. an abelian variety) then we use Corollary 2.13 (resp. Corollary 2.27) to prove that the sets $\mathcal{F}_i$ are contained in a finite union of tacs of $G$ of dimension $\leq d - i$.

This finally concludes the proof. \qed

51
CHAPTER 3

Tannakian categories of perverse sheaves

Throughout this chapter, \( k \) denotes a finite field and \( \bar{k} \) an algebraic closure of \( k \). We denote by \( \ell \) a prime number different from the characteristic of \( k \). All complexes we consider are \( \ell \)-adic complexes.

Let \( G \) be a connected commutative algebraic group over \( k \).

We denote by \( \mathbf{D}(G) \) and \( \mathbf{P}(G) \) the full subcategories of \( D^b_c(G_{\bar{k}}) \) and \( \text{Perv}(G_{\bar{k}}) \) respectively whose objects are defined over some finite extension of the base field \( k \). These categories are stable by direct sum, shifts and duality. Moreover, the perverse cohomology sheaves of an object of \( \mathbf{D}(G) \) belong to \( \mathbf{P}(G) \).

We recall from Section 1.4 the definition and properties of the two convolutions bifunctors \((M,N) \mapsto M^\ast N \) and \((M,N) \mapsto M^! N \) for objects \( M \) and \( N \) of \( D^b_c(G) \) or \( D^b_c(G_{\bar{k}}) \). These are compatible with base change, so that the convolutions on \( G_{\bar{k}} \) preserve the category \( \mathbf{D}(G) \). In addition, the functor \( M \mapsto M^\vee \) also induces a functor on \( \mathbf{D}(G) \) and \( \mathbf{P}(G) \).

3.1. Weakly unramified characters

**Definition 3.1 (Weakly unramified characters).** Let \( M \) be an object of \( \mathbf{P}(G) \). A character \( \chi \in \hat{G} \) is said to be \emph{weakly unramified} for \( M \) if the following holds:

\[
H^i(G_{\bar{k}}, M_\chi) = H^i_c(G_{\bar{k}}, M_\chi) = 0 \quad \text{for all } i \neq 0,
\]

\[
H^0(G_{\bar{k}}, M_\chi) = H^0(G_{\bar{k}}, M_\chi).
\]

We denote by \( \mathcal{X}_w(M) \) the set of weakly unramified characters for \( M \).

**Remark 3.2.** The terminology is suggested by analogy with the case of the additive group, in which the characters for which generic vanishing holds correspond to points at which the Fourier transform is lisse. However, we will see that the generic vanishing condition is not in general strong enough to obtain the properties we seek (namely, that the assignment \( M \mapsto H^0_c(G_{\bar{k}}, M_\chi) \) defines a fiber functor on a suitable tannakian category of perverse sheaves on \( G_{\bar{k}} \)). We will introduce unramified characters in Definition 3.24, as well as the variant of Frobenius-unramified characters in Definition 3.34.

With this definition, we can reformulate the Stratified Generic Vanishing Theorem 2.1 as follows:

**Theorem 3.3.** The subset \( \mathcal{X}_w(M) \subset \hat{G} \) of weakly unramified characters for an object \( M \) of \( \mathbf{P}(G) \) is generic.

3.2. Negligible objects

In general, none of the two convolution bifunctors on the derived category preserves the subcategory of perverse sheaves. As first observed in the case of tori by Gabber and Loeser [46], there is however a suitable quotient of the category \( \mathbf{P}(G) \) on which both convolution functors induce the same bifunctor.
DEFINITION 3.4. An object M of \( \text{P}(G) \) is said to be negligible if the set of characters \( \chi \in \hat{G} \) satisfying \( H^i(G, M) = 0 \) for all \( i \) is generic. An object N of \( \text{D}(G) \) is said to be negligible if all its perverse cohomology objects \( \mathcal{H}^i(N) \) are negligible.

We denote by \( \text{Neg}_{\text{P}}(G) \) and \( \text{Neg}_{\text{D}}(G) \) the full subcategories of \( \text{P}(G) \) and \( \text{D}(G) \) respectively consisting of negligible objects.

We denote by \( K_{\text{neg}}(G) \) the subgroup of the Grothendieck group \( K(G) \) generated by classes of negligible perverse sheaves, or equivalently by classes of negligible objects.

Given an object M of \( \text{P}(G) \), set
\[
\mathcal{N}(M) = \{ \chi \in \hat{G} \mid H^i(G, M) = 0 \text{ for all } i \}.
\]

Using Theorem 3.3, we see that M is negligible if and only if \( \mathcal{N}(M) \) is a generic subset of \( \hat{G} \). For \( M \in \text{Neg}_{\text{D}}(G) \), we set
\[
\mathcal{N}(M) = \bigcup_i \mathcal{N}(\mathcal{H}^i(M)).
\]

It follows from the definition that, for each negligible perverse sheaf M (resp. object of \( \text{Neg}_{\text{D}}(G) \)), the perverse sheaf \( M^\vee \) is also negligible (resp. the complex \( M^\vee \) is negligible).

EXAMPLE 3.5. Any character sheaf \( \mathcal{L}_\chi \) on G is negligible. More generally, let \( f: G \to H \) be a surjective morphism of algebraic groups such that the dimension \( d \) of the kernel \( \ker(f) \) is positive. Let \( \eta \in \hat{G} \) and let N be any object of \( \text{D}^\text{b}(H) \). We claim that the object \( M = (f^*N)_\eta \) is negligible.

Indeed, let \( i \in \mathbb{Z} \). We can factor \( f = f_1 \circ f_2 \), where \( f_2 \) is smooth of relative dimension \( d \) and \( f_1 \) is radicial. Then \( f_2^*[d] \) is t-exact (see [6, §4.2.4]), and so is tensoring by \( \mathcal{L}_\eta \) (Lemma 1.17), so there is a canonical isomorphism
\[
\mathcal{H}^i((f^*N)_\eta) \simeq f_2^*(\mathcal{H}^{i-d}(N))_\eta.
\]

For \( \chi \in \hat{G} \), the projection formula leads to canonical isomorphisms
\[
H^*(G_k, M_\chi) \simeq H^*(G_k, f_2^*(\mathcal{H}^{i-d}(N)) \otimes \mathcal{L}_\eta) \simeq H^*(H_k, \mathcal{H}^{i-d}(N) \otimes Rf_2!\mathcal{L}_\eta).
\]

The complex \( Rf_2!\mathcal{L}_\eta \) is zero if the restriction of \( \eta \chi \) to the subgroup \( \ker(f_2)^\circ \) is not the trivial character (see Lemma 1.16). Since this condition defines a generic set of characters \( \chi \), we deduce that \( \mathcal{H}^i(M) \) is negligible, and the result follows.

REMARK 3.6. Intuitively, to say that M is negligible means that the arithmetic Fourier transform of M (see Section 1.7) satisfies \( S(M, \chi) = 0 \) for \( \chi \) in a generic subset of \( \hat{G} \). To illustrate this concrete aspect, we show how it explains the previous example. Thus consider \( M = (f^*N)_\eta \), with notation as above for some \( \eta \in \hat{G}(k) \). Let \( \chi \in \hat{G}(k_n) \); the corresponding value of the Fourier transform is
\[
S(M, \chi) = \sum_{x \in G(k_n)} \chi(x)t_M(x; k_n) = \sum_{x \in G(k_n)} \chi(x)(\eta \circ N_{k_n/k})(x)t_N(f(x); k_n)
\]
\[
= \sum_{y \in H(k_n)} t_N(y; k_n) \sum_{x \in G(k_n) \atop f(x) = y} \chi(\eta \circ N_{k_n/k})(x),
\]

and the inner sum is either empty or a sum of a character over the \( k_n \)-points of a coset of the kernel of \( f \), which vanishes unless \( \chi = (\eta \circ N_{k_n/k})^{-1} \) on the kernel of \( f \).

In some cases, one can show that, conversely, all simple negligible perverse sheaves are of the form \( (f^*N)_\eta \) for some quotient morphism \( f \) with kernel of dimension at least 1. This is for instance the case for abelian varieties, by a result of Weissauer [113, Lemma 6, Th. 3] (see also Remark 5.13) and we will prove later that this is also the case for \( G_a \times G_m \) (see Section 10.4).
This structural property is however not always true. For instance, if \( G \) is a unipotent group of dimension at least 2 (e.g., \( G = G^d_a \) with \( d \geq 2 \)), with Serre dual \( G^\vee \), then we can take any object \( N \in D^b_c(G^\vee) \) whose support \( S \) has codimension at least 1, and the inverse Fourier transform \( M \) of \( N \) will be a negligible object on \( G \). If \( S \) is not a translate of a subgroup of \( G \), then the object \( M \) is not obtained by pullback from any quotient of \( G \). (In the terminology of \([35, \S 4]\), in the case of \( G^d_a \), such objects are said to have A-number equal to 0, and they play a delicate role in certain analytic applications.)

We recall that a full subcategory \( S \) of an abelian category \( C \) is said to be a **Serre subcategory** if it is not empty, stable by extension and by subobject and quotient. A strictly full triangulated subcategory \( S \) of a triangulated category \( C \) is said to be **thick** if, for any morphism \( f : X \to Y \) in \( C \) which factors through an object of \( S \), and which appears in a distinguished triangle

\[
X \xrightarrow{f} Y \to Z
\]

with \( Z \) object of \( S \), the objects \( X \) and \( Y \) are in \( S \).

**Lemma 3.7.** The category \( \text{Neg}_{P}(G) \) is a Serre subcategory of \( P(G) \), and \( \text{Neg}_{D}(G) \) is a thick triangulated subcategory of \( D(G) \).

**Proof.** Fix an exact sequence \( X \to Y \to Z \) in \( P(G) \) such that \( X \) and \( Z \) are objects of \( \text{Neg}_{P}(G) \). By Theorem 3.3, there is a generic set of characters \( \chi \in \hat{G} \) that are weakly unramified for \( X \), \( Y \), and \( Z \). From the long exact sequence in cohomology, we find that for any such \( \chi \), the vanishing \( H^i(G^\vee_k, Y_\chi) = H^i_c(G^\vee_k, Y_\chi) = 0 \) holds for all \( i \), and hence \( Y \) is negligible. The first statement follows easily. An argument of Gabber–Loeser (see [46, Prop. 3.6.1(i)]) then implies that \( \text{Neg}_{D}(G) \) is a thick triangulated subcategory of \( D(G) \). \( \square \)

**Lemma 3.8.** For all objects \( M \) and \( N \) of \( D(G) \), the following properties hold:

1. The cone of the canonical morphism \( M \ast_! N \to M \ast_* N \) lies in \( \text{Neg}_{D}(G) \).
2. If \( M \) belongs to \( \text{Neg}_{D}(G) \), then so do \( M \ast_! N \) and \( M \ast_* N \) for each object \( N \).
3. If \( M \) and \( N \) belong to \( P(G) \), then \( p_\mathcal{H}^i(M \ast_! N) \) and \( p_\mathcal{H}^i(M \ast_* N) \) lie in \( \text{Neg}_{P}(G) \) for each non-zero integer \( i \).

We omit the proof, which is the same as that of [81, Lem. 4.3].

### 3.3. Tannakian categories

By results of Gabriel [47] for abelian categories and Verdier (see the treatment in the book [95] of Neeman) for triangulated categories, we can define the quotient of an abelian or triangulated category by a Serre or thick subcategory. This allows us to make the following definition.

**Definition 3.9 (Convolution categories).** The convolution category of \( G \), denoted \( D(G) \), is the quotient category of \( D(G) \) by \( \text{Neg}_{D}(G) \); it is a triangulated category.

The perverse convolution category of \( G \), denoted \( P(G) \), is the quotient abelian category of \( P(G) \) by \( \text{Neg}_{P}(G) \).

Those two constructions are compatible, in the sense that the t-structure on \( D(G) \) induces a t-structure on \( D(G) \) whose heart is the category \( P(G) \) (see [46, Prop. 3.6.1]).

Since the functor \( N \mapsto N^\vee \) preserves negligible objects, it induces a functor on \( P(G) \) (resp. on \( D(G) \)), which is still an involution.

**Proposition 3.10.** With notation as above, the following properties hold:
The convolution products \( \ast_t \) and \( \ast_s \) induce bifunctors on \( \mathcal{D}(G) \times \mathcal{D}(G) \).

The canonical forget support morphisms \( M \ast_t N \to M \ast_s N \) induce isomorphisms in \( \mathcal{D}(G) \), and define by passing to the quotient a convolution bifunctor denoted 
\[ * : \mathcal{D}(G) \times \mathcal{D}(G) \to \mathcal{D}(G). \]

(3) The subcategory \( \mathcal{P}(G) \) of \( \mathcal{D}(G) \) is stable under the convolution \( * \).

(4) The categories \( \mathcal{D}(G) \) and \( \mathcal{P}(G) \), endowed with the bifunctor \( * \), are symmetric \( \mathbb{Q}_l \)-linear monoidal categories with unit object \( 1 \) the image of the skyscraper sheaf at the neutral element of \( G \).

**Proof.** The fact that \( \ast_t \) and \( \ast_s \) induce functors on \( \mathcal{D}(G) \times \mathcal{D}(G) \) follows from Lemma 3.8 (2). That they agree is Lemma 3.8 (1). The stability of \( \mathcal{P}(G) \) under \( * \) is Lemma 3.8 (3). The fact that we obtain symmetric \( \mathbb{Q}_l \)-linear monoidal categories is now clear. The last assertion follows from the canonical isomorphisms \( 1 \ast_t M \simeq 1 \ast_s M \simeq M \) which exist for any complex \( M \). \( \square \)

It is also very useful that there exists a natural subcategory of \( \mathcal{P}(G) \) that is equivalent to the perverse convolution category.

**Definition 3.11.** The internal convolution category of \( G \) is the full subcategory \( \mathcal{P}_{\text{int}}(G) \) of the category \( \mathcal{P}(G) \) whose objects are perverse sheaves that have no subobject or quotient in \( \text{Neg}_{\mathcal{P}}(G) \).

**Proposition 3.12.** The localization functor \( \mathcal{P}(G) \to \mathcal{P}(G) \) restricts to an equivalence of categories \( \mathcal{P}_{\text{int}}(G) \to \mathcal{P}(G) \), hence the convolution product bifunctor \( * \) on \( \mathcal{P}(G) \) induces a convolution bifunctor \( *_{\text{int}} \) on \( \mathcal{P}_{\text{int}}(G) \).

**Proof.** The argument is the same as that of Gabber and Loeser [46, Déf.-Prop. 3.7.2]. \( \square \)

The convolution product on \( \mathcal{P}_{\text{int}}(G) \) will sometimes be called the internal or middle convolution.

**Remark 3.13.** One can give a more explicit form of the equivalence of categories above, and of the internal convolution.

First, Gabber and Loeser (loc. cit.) give an explicit quasi-inverse functor \( M \mapsto M_{\text{int}} \) to the equivalence of categories \( \mathcal{P}_{\text{int}}(G) \to \mathcal{P}(G) \). Namely, let \( M \) be an object of \( \mathcal{P}(G) \). Let \( M_t \) be the largest subobject of \( M \) that belongs to \( \text{Neg}_{\mathcal{P}}(G) \) and let \( M_t' \) be the smallest subobject of \( M \) such that \( M/M_t' \) belongs to \( \text{Neg}_{\mathcal{P}}(G) \). Define \( M_{\text{int}} = M_t/(M_t \cap M_t) \). Then we have canonical isomorphisms 
\[ M_{\text{int}} \simeq (M_t + M_t)/M_t, \]
and the assignment \( M \mapsto M_{\text{int}} \) is a functor which factors through \( \mathcal{P}(G) \) and induces a quasi-inverse of the localization functor.

In particular, this implies that if \( M \) is a semisimple object of \( \mathcal{P}(G) \), then \( M_{\text{int}} \) is the sum of all the simple constituents of \( M \) that are not in \( \text{Neg}_{\mathcal{P}}(G) \).

Second, it follows from the argument in [46, Déf.-Prop. 3.7.3] that for \( M \) and \( N \) in \( \mathcal{P}_{\text{int}}(G) \), there are canonical isomorphisms 
\[ M \ast_{\text{int}} N \to \mathcal{p} \mathcal{H}^0(M \ast_t N)_{\text{int}} \to \mathcal{p} \mathcal{H}^0(M \ast_s N)_{\text{int}}. \]

From the adjunctions in Lemma 1.15 (1), we see that for all \( M \in \mathcal{P}(G) \), the identity morphism \( \text{id}_M : M \to M \) defines evaluation and coevaluation maps 
\[ \text{ev} : M \ast_t M^\vee \to 1 \quad \text{and} \quad \text{coev} : 1 \to M^\vee \ast_s M. \]
They correspond to maps in \( \mathcal{P}(G) \) which we denote in the same way.
Proposition 3.14. The monoidal category \( \mathcal{P}(G) \) is rigid. That is, for each object \( M \) of \( \mathcal{P}(G) \), the morphisms
\[
\begin{align*}
M &\cong M \ast 1 \\
M^\vee &\cong 1 \ast M^\vee \\
M &\cong 1 \ast M \\
M^\vee &\cong 1 \ast M^\vee
\end{align*}
\]
are the identity on \( M \) and on \( M^\vee \) respectively.

Proof. The argument is the same as that of Krämer in [81, Th. 5.2]. □

For any object \( M \) of \( \mathcal{P}(G) \) (resp. of \( \mathcal{P}_{\text{int}}(G) \)), we denote by \( \langle M \rangle \) the subcategory of \( \mathcal{P}(G) \) (resp. of \( \mathcal{P}_{\text{int}}(G) \)) which is tensor-generated by \( M \), i.e., the full subcategory whose objects are the subquotients of all convolution powers of \( M \oplus M^\vee \).

Our next goal is to prove the following crucial result:

Theorem 3.15. The categories \( \mathcal{P}(G) \) and \( \mathcal{P}_{\text{int}}(G) \) are neutral tannakian categories.

In particular, for any object \( M \) of \( \mathcal{P}_{\text{int}}(G) \) or of \( \mathcal{P}(G) \), the category \( \langle M \rangle \) is a neutral tannakian category over \( \overline{Q}_\ell \).

Recall that this means that there exists a fiber functor, namely a faithful exact tensor functor from \( \mathcal{P}(G) \) to the category Vect_{\overline{Q}_\ell} of finite dimensional \( \overline{Q}_\ell \)-vector spaces.

We begin the proof with an auxiliary result. Recall that the trace \( \text{Tr}(f) \in \overline{Q}_\ell = \text{End}(1) \) of an endomorphism \( f \) of \( M \in \mathcal{P}_{\text{int}}(G) \) is defined as the composition
\[
1 \xrightarrow{1 \text{coev}} M \ast \text{int} M^\vee \xrightarrow{f \ast \text{int} \text{id}_M^\vee} M \ast \text{int} M^\vee \xrightarrow{\text{id}_M^\vee \text{ev}} 1.
\]

The dimension of \( M \in \mathcal{P}_{\text{int}}(G) \) is then intrinsically defined as \( \dim(M) = \text{Tr}(\text{id}_M) \). It is, a priori, an element of \( \overline{Q}_\ell \).

Proposition 3.16. Let \( M \) be an object of \( \mathcal{P}_{\text{int}}(G) \) and let \( C \) be the cone of the canonical morphism
\[
M \ast 1 \rightarrow M^\vee.
\]
For any character \( \chi \in \hat{G} \) in the generic set
\[
\mathcal{X}_w(M) \cap \mathcal{N}(C),
\]
the following equality holds:
\[
\dim H^0(G_{\overline{k}}, M_{\chi}) = \dim(M).
\]

In particular, \( \dim(M) \) is a non-negative integer, and there exists a generic set of characters \( \chi \) such that the dimension of \( H^0(G_{\overline{k}}, M_{\chi}) \) is independent of \( \chi \).

Proof. We need to determine the morphism
\[
1 \xrightarrow{1 \text{coev}} M \ast \text{int} M^\vee \xrightarrow{\text{ev}} 1.
\]

Twisting by \( \chi \) and taking cohomology, the sequence above induces a sequence
\[
\overline{Q}_\ell \rightarrow H^*(G_{\overline{k}}, (M \ast \text{int} M^\vee)_\chi) \rightarrow \overline{Q}_\ell.
\]

By Lemma 3.8, the object \( C \) is in \( \text{Neg}_{\mathcal{D}}(G) \) so that for \( \chi \in \mathcal{N}(C) \), we have a canonical isomorphism
\[
H^*(G_{\overline{k}}, (M \ast \text{int} M^\vee)_\chi) \cong H^*(G_{\overline{k}}, (M \ast \text{int} M^\vee)_\chi).
\]
By Lemma 1.15, there is also a canonical isomorphism

$$H^*(\mathbb{G}_k, (M*: M^v)_\chi) \cong H^*(\mathbb{G}_k, M_\chi) \otimes H^*(\mathbb{G}_k, (M_\chi)^v),$$

If $$\chi \in p_w(M),$$ then we also get $$H^*(\mathbb{G}_k, M_\chi) = H^0(\mathbb{G}_k, M_\chi)$$ and $$H^*(\mathbb{G}_k, (M_\chi)^v) = H^0(\mathbb{G}_k, (M_\chi)^v),$$ and therefore the sequence above becomes

$$\overline{Q}_\ell \to \text{End}(H^0(\mathbb{G}_k, M_\chi)) \to \overline{Q}_\ell.$$

Since the evaluation and coevaluation maps are sent to evaluation and coevaluation maps in vector spaces (see the proof of [81, Th.5.2]), this composition is the multiplication by the dimension of $$H^0(\mathbb{G}_k, M_\chi),$$ which is therefore equal to the dimension of $$M$$ in $$P_{\text{int}}(G).$$

**Proof of Theorem 3.15.** By Proposition 3.14, the equivalent categories $$\overline{P}(G)$$ and $$P_{\text{int}}(G)$$ are $$\overline{Q}_\ell$$-linear rigid tensor symmetric categories. Since the unit $$1$$ is (the image of) a skyscraper sheaf, we have $$\text{End}(1) \cong \overline{Q}_\ell.$$

Proposition 3.16 and Theorem 3.3 imply that the dimension $$\text{dim}(M)$$ of every object $$M$$ of $$\overline{P}(G)$$ is a non-negative integer. By a theorem of Deligne [29, Th.7.1], it follows that the category $$\overline{P}(G)$$ is a tannakian category. A further theorem of Deligne (see the proof by Coulembier in [22, Th.6.4.1]) implies that it is indeed neutral (i.e., there exists a fiber functor defined over $$\overline{Q}_\ell$$).

**Remark 3.17.**

1. In Example 10.13, we will give examples to show that there may exist unramified characters for which formula (3.1) does not hold.

2. In this book, we will exclusively consider from now on the categories $$\langle M \rangle$$ generated by a single object. A simpler proof that these are neutral tannakian categories is then provided by combining [29, Th.7.1] with [29, Cor.6.20].

**Corollary 3.18.** Let $$M$$ be an object of $$P_{\text{int}}(G).$$ There exists an affine algebraic group $$\mathbb{G}$$ over $$\overline{Q}_\ell$$ such that the category $$\langle M \rangle$$ is equivalent to the category $$\text{Rep}(\mathbb{G})$$ of finite-dimensional $$\overline{Q}_\ell$$-representations of $$\mathbb{G}.$$ If $$M$$ is semisimple, then the group $$\mathbb{G}$$ is reductive and the category $$\langle M \rangle$$ is semisimple.

**Proof.** The first part follows from the tannakian reconstruction theorem [30, Th.2.11]. If $$M$$ is semisimple then since the category of representations of $$\mathbb{G}$$ is equivalent to the category $$\langle M \rangle$$ generated by the semisimple object $$M,$$ it follows, e.g., from [94, Th.22.42] that the group $$\mathbb{G}$$ is reductive, and that every object $$N \in \langle M \rangle$$ is semisimple.

**Definition 3.19.** For any object $$M$$ of $$P_{\text{int}}(G)$$ or of $$\overline{P}(G),$$ we denote by $$\mathbb{G}^\text{geo}_M$$ the affine algebraic group over $$\overline{Q}_\ell$$ given by the corollary, and we say that it is the geometric tannakian group of the object $$M.$$

**Example 3.20.**

1. Let $$\mathbb{G} = \mathbb{G}_m.$$ A perverse sheaf $$N$$ on $$\mathbb{G}_m$$ is negligible if and only if it has no subobject or quotient which is isomorphic to a shifted Kummer sheaf $$\mathcal{L}_\chi[1]$$ for some character $$\chi,$$ and it follows that the category $$P_{\text{int}}(\mathbb{G}_m)$$ is the same as the category $$\mathcal{P}$$ of Katz (defined in [68, Ch.2]; see also Section B.1).

2. Let $$\mathbb{G} = \mathbb{G}_a.$$ Fix an additive character $$\psi$$ of $$k.$$ By the proper base change theorem, a perverse sheaf $$N$$ on $$\mathbb{G}_a$$ is negligible if and only if its Fourier transform $$\text{FT}_\psi(N)$$ is punctual, which means that $$N$$ is a finite direct sum of Artin–Schreier sheaves $$\mathcal{L}_{\psi(y)[x]}[1]$$ for some $$y \in \mathbb{G}_a.$$ This implies that the category $$P_{\text{int}}(\mathbb{G}_a)$$ coincides with the category of perverse sheaves on $$\mathbb{G}_a$$ with property $$\mathcal{P},$$ as defined by Katz again (this follows by combining Cor. 2.6.14, Cor. 2.6.15 and Lemma 2.6.13 of [63]; see Remark 2.10.4 in loc. cit.).
3.4. Euler–Poincaré characteristic and Grothendieck groups

Proposition 3.16 has some other useful corollaries which we state now.

**Proposition 3.21.** Let $M$ be an object of $D^b_c(G)$.

1. There exists a generic set $\mathcal{X} \subset \hat{G}$ such that the Euler–Poincaré characteristic $\chi(G_\bar{k}, M_\chi)$ is independent of $\chi \in \mathcal{X}$.

2. If $M$ is negligible, then $\chi(G_\bar{k}, M_\chi) = 0$ for all $\chi$ in a generic set of characters. The converse holds if $M$ is a perverse sheaf.

3. If $G$ is a semiabelian variety, then the Euler–Poincaré characteristic $\chi(G_\bar{k}, M_\chi)$ is independent of $\chi \in \mathcal{X}$ and it is non-negative if $M$ is a perverse sheaf.

**Proof.** The decomposition

$$M = \sum_{i \in \mathbb{Z}} (-1)^i \mathcal{H}^i(M)$$

in the Grothendieck group $K(G)$, together with Lemma 1.17, implies that

$$\chi(G_\bar{k}, M_\chi) = \sum_{i \in \mathbb{Z}} (-1)^i \chi(G_\bar{k}, \mathcal{H}^i(M)_\chi)$$

for all $\chi \in \hat{G}$. Thus the first statement is an immediate consequence of Proposition 3.16, combined with the generic vanishing theorem, applied to each perverse cohomology sheaf.

If $N$ is a negligible perverse sheaf, then by definition we get $H^*(G_\bar{k}, N_\chi) = 0$ for a generic set of characters, hence also $\chi(G_\bar{k}, N_\chi) = 0$ for a generic set of characters. The previous formula shows that this is also true for any complex $M$.

Conversely, assume that $M$ is a perverse sheaf and $\chi(G_\bar{k}, M_\chi) = 0$ for all $\chi$ in a generic set. Combined with the generic vanishing theorem, this implies that $H^*(G_\bar{k}, M_\chi) = 0$ for $\chi$ generic, hence $M$ is negligible.

If $G$ is a semiabelian variety, then the Euler–Poincaré characteristic $\chi(G_\bar{k}, M_\chi)$ is independent of $\chi$ by a result of Deligne (see [58]), because all the $\chi \in \hat{G}$ are tame. In this case, the tannakian dimension of a perverse sheaf on $G$ is therefore the same as its Euler–Poincaré characteristic.

**Corollary 3.22.** A perverse sheaf $M$ in $P(G)$ is negligible if and only if its class in the Grothendieck group $K(G)$ belongs to the subgroup $K_{\text{neg}}(G)$ generated by classes of negligible perverse sheaves.

**Proof.** It suffices to prove that a perverse sheaf $M$ is negligible if the class of $M$ in $K(G)$ can be expressed as a finite sum

$$M = \sum_{i \in I} \varepsilon_i M_i$$

in $K(G)$, where $M_i$ is a negligible perverse sheaf for all $i \in I$ and $\varepsilon_i \in \{-1, 1\}$. Such a formula implies the equality

$$\chi(G_\bar{k}, M_\chi) = \sum_{i \in I} \varepsilon_i \chi(G_\bar{k}, M_i_\chi)$$

for all $\chi \in \hat{G}$. For a generic set of characters we have $\chi(G_\bar{k}, M_i_\chi) = 0$ for all $i \in I$, since $M_i$ is negligible by assumption, hence $\chi(G_\bar{k}, M_\chi) = 0$ for a generic set of characters; thus $M$ is negligible by Proposition 3.21, (2).
Corollary 3.23. Suppose that $G$ is a semiabelian variety. Let $M$ be a negligible perverse sheaf on $G$. The Euler–Poincaré characteristic of $M$ is 0 and the set of characters $\chi \in \hat{G}$ such that the space $H^0(G, M_{\chi})$ is non-zero is contained in a finite union of tacs.

Proof. The fact that $\chi(M) = 0$ has been stated in Proposition 3.21. By Theorem 2.16, there exists a finite family $(S_f)$ of tacs of $G$ such that $H^i(G, M_{\chi}) = 0$ for all $i \neq 0$ and $\chi$ not belonging to the union $\mathcal{S}$ of these tacs. For any $\chi$ not in $\mathcal{S}$, we then deduce by loc. cit. that

$$\dim H^0(G, M_{\chi}) = \chi(M \chi) = \chi(M) = 0.$$  

\[ \square \]

3.5. Arithmetic fiber functors

We now address the question of constructing arithmetic fiber functors that will be used to define conjugacy classes of elements in the tannakian groups.

Definition 3.24 (Unramified characters). Let $M$ be an object of $P_{\text{int}}(G)$. A weakly unramified character $\chi \in \hat{G}$ for $M$ is said to be unramified for $M$ if the functor

$$N \mapsto \omega_{\chi}(N) = H^0(G, N_{\chi})$$

is a fiber functor on the category $\langle M \rangle$. We denote by

$$\mathcal{X}(M) \subset \mathcal{X}_{w}(M) \subset \hat{G}$$

the set of unramified characters for $M$. We say that the perverse sheaf $M$ is generically unramified if the subset $\mathcal{X}(M) \subset \hat{G}$ is generic.

We expect that all semisimple objects of $P_{\text{int}}(G)$ are generically unramified. We can currently only prove this property for the three fundamental types of algebraic groups.

Theorem 3.25. If $G$ is a torus, an abelian variety or a unipotent group, then any semisimple object of $P_{\text{int}}(G)$ is generically unramified.

For tori or abelian varieties, we need a general technical criterion ensuring that an object $M$ is generically unramified.

Lemma 3.26. Let $M$ be a semisimple object of $P_{\text{int}}(G)$. Set $L = M \oplus M^\vee$. For each $m \geq 2$, let $C_m$ be the cone of the canonical morphism $L^{\otimes m}_\text{int} \to L^{*\otimes m}_\text{int}$. All characters $\chi$ in

$$\mathcal{X}_w(M) \cap \bigcap_{m \geq 2} \mathcal{N}(C_m)$$

are unramified for $M$.

Proof. Let $\chi$ be a character in the set (3.2). By Proposition 1.30, every object $N$ of $\langle M \rangle$ is a direct sum of direct factors of $m$-fold convolution products $L^{\otimes m}_\text{int}$ for some integers $m$. By the definition of (3.2) and Lemma 1.15, we have canonical isomorphisms

$$H^\ast(G, L^{\otimes m}_\text{int}) \simeq H^\ast(G, L^{*\otimes m}_\text{int}) \simeq H^\ast(G, L_{\chi}^{\otimes m})$$

for any $m$.

By (3.2) again, we have $H^\ast(G, L_{\chi}) = H^0(G, L_{\chi})$, and hence $\omega_{\chi}(L^{\otimes m}_\text{int}) = \omega_{\chi}(L)^{\otimes m}$. This proves that the functor $\omega_{\chi}$ is compatible with the tensor product; other compatibilities are elementary, and the functor $\omega_{\chi}$ is exact on $\langle M \rangle$, hence the result (see [30, Prop. 1.19]).  

\[ \square \]
Proof of Theorem 3.25 for abelian varieties. If $G$ is an abelian variety, then both convolution functors are canonically isomorphic; hence, all objects $C_m$ vanish and the set (3.2) is the same as $\mathcal{X}_w(M)$, which is generic. □

Remark 3.27. There is a more precise result if $G$ is an abelian variety. Indeed, we have recalled that $\mathcal{X}_w(M) = \mathcal{X}(M)$ for any semisimple object of $\mathcal{P}_{\text{int}}(G)$, and by the strong form of the Stratified Generic Vanishing Theorem (Theorem 2.3), it follows that the set of ramified characters is contained in a finite union of tacs of $G$.

Proof of Theorem 3.25 for tori. We use the notation of the previous lemma. For a torus $G$, a result of Gabber and Loeser [46, Prop. 3.9.3 (iv)] implies that there is an inclusion $N(C_2) \subset N(C_m)$ for all integers $m \geq 2$. So the set $\mathcal{X}_w(M) \cap \bigcap_{m \geq 2} N(C_m) = \mathcal{X}_w(M) \cap N(C_2)$ is generic, by the generic vanishing theorem and the definition of negligible objects. □

Finally we consider unipotent groups.

Proof of Theorem 3.25 for $G$ unipotent. We denote by $G^\vee$ a form of the Serre dual of $G$, and we fix an additive character $\psi$ to compute the Fourier transform $\text{FT}_\psi$ on $G$ (see Section 2.2).

Let $M$ be a semisimple object of $\mathcal{P}_{\text{int}}(G)$. We claim that there exists a dense open set $V \subset G^\vee$ such that for every objects $N$ and $N'$ of $\langle M \rangle$, the restriction of $\text{FT}_\psi(N)$ to $V$ is lisse and there exists a canonical isomorphism

$$\text{FT}_\psi(N \ast_{\text{int}} N')|V \rightarrow (\text{FT}_\psi(N) \otimes \text{FT}_\psi(N'))|V.$$  

Indeed, if this claim holds, then it is elementary that for any $a \in V(\overline{k})$, the corresponding character $\psi_a \in \hat{G}$ is unramified for $M$.

The claim above follows in turn from a more general statement: for every objects $M_1$ and $M_2$ of $\mathcal{P}_{\text{int}}(G)$, and for any open dense subset $W \subset G^\vee$ such that the Fourier transforms $\text{FT}_\psi(M_1)$ and $\text{FT}_\psi(M_2)$ are lisse on $W$, there exists a canonical isomorphism

$$\text{FT}_\psi(M_1 \ast_{\text{int}} M_2)|W \rightarrow (\text{FT}_\psi(M_1) \otimes \text{FT}_\psi(M_2))|W.$$  

Indeed, the isomorphism shows in particular that the Fourier transform of $M_1 \ast_{\text{int}} M_2$ is also lisse on $W$; since the same is true of the dual $D(M_1)$, it follows that the Fourier transform of any object of $\langle M_1 \rangle$ is lisse on $W$, leading to the previous claim (with $V = W$).

We now prove the general statement above. Let $M = p_{\mathcal{H}^0}(M_1 \ast_1 M_2)$. By definition of $M_1 \ast_{\text{int}} M_2$, we have $M_1 \ast_{\text{int}} M_2 = M_{\text{int}}$ (see Remark 3.13).

Let $p_{\tau \leq 0}$ and $p_{\tau \geq 0}$ be the perverse truncation functors. We have canonical morphisms

$$p_{\tau \leq 0}(M_1 \ast_1 M_2) \rightarrow M_1 \ast_1 M_2$$  

and

$$p_{\tau \leq 0}(M_1 \ast_1 M_2) \rightarrow p_{\tau \geq 0}(p_{\tau \leq 0}(M_1 \ast_1 M_2)) = p_{\mathcal{H}^0}(M_1 \ast_1 M_2) = M.$$  

By Lemma 3.8, the mapping cones of both morphisms are negligible. By the vanishing theorem for unipotent groups (Proposition 2.7), there is a dense open subset $W'$ of $W$ such that the induced morphisms

$$\text{FT}_\psi(p_{\tau \leq 0}(M_1 \ast_1 M_2))|W' \rightarrow \text{FT}_\psi(M_1 \ast_1 M_2)|W'.$$  

and

\[(3.7) \quad \text{FT} \psi(^p\tau_{\leq 0}(M_1 \boxtimes M_2))|W' \to \text{FT} \psi(M)|W'\]

are isomorphisms. Inverting (3.6) and composing with (3.7), we obtain a canonical isomorphism

\[(3.8) \quad \text{FT} \psi(M_1 \boxtimes M_2)|W' \to \text{FT} \psi(M)|W'.\]

Recall from Remark 3.13 that if \(M'\) is the smallest subobject of \(M\) such that \(M/M'\) is negligible, then we have a canonical injection \(M' \to M\) with negligible cokernel and a canonical surjection \(M' \to M_{\text{int}}\) with negligible kernel. By the vanishing theorem for unipotent groups (Proposition 2.7), up to replacing \(W'\) by a smaller dense open subset, we can assume that the canonical morphisms

\[(3.9) \quad \text{FT} \psi(M')|W' \to \text{FT} \psi(M)|W'\]

are isomorphisms. Inverting (3.9) and composing with (3.10), we get a canonical isomorphism

\[(3.10) \quad \text{FT} \psi(M')|W' \to \text{FT} \psi(M_{\text{int}})|W'.\]

Since \(\text{FT} \psi(M)|W' \to \text{FT} \psi(M_{\text{int}})|W' = \text{FT} \psi(M_1 \boxtimes M_2)|W'.\)

Composing (3.8) and (3.11), we get a canonical isomorphism

\[(3.11) \quad \text{FT} \psi(M_1 \boxtimes M_2)|W' \simeq \text{FT} \psi(M_1 \boxtimes M_2)|W'.\]

Denote by \(j: W' \to W\) the open immersion. By the definition of the category \(\text{P}_{\text{int}}(G)\), the Fourier transform \(\text{FT} \psi(M_1 \boxtimes M_2)\) (which is a perverse sheaf up to shift) has no shifted perverse component supported in \(G' - W'\) (such a component would be negligible), and therefore we have a canonical isomorphism

\[(3.12) \quad j_{!*}j^*(\text{FT} \psi(M_1 \boxtimes M_2)|W) \simeq \text{FT} \psi(M_1 \boxtimes M_2)|W\]

by the properties of the intermediate extension functor \(j_{!*}\) (see Proposition A.9).

By Lemma 1.15, there is a canonical isomorphism \(\text{FT} \psi(M_1 \boxtimes M_2) \simeq \text{FT} \psi(M_1) \otimes \text{FT} \psi(M_2)\). Since \(\text{FT} \psi(M_1)\) and \(\text{FT} \psi(M_2)\) are lisse on \(W\), we have also a canonical isomorphism

\[(3.13) \quad j_{!*}j^*(\text{FT} \psi(M_1) \otimes \text{FT} \psi(M_2)|W) \simeq (\text{FT} \psi(M_1) \otimes \text{FT} \psi(M_2))|W,\]

hence a canonical isomorphism

\[(3.14) \quad j_{!*}j^*(\text{FT} \psi(M_1 \boxtimes M_2)|W) \simeq (\text{FT} \psi(M_1) \otimes \text{FT} \psi(M_2))|W.\]

We now apply the functor \(j_{!*}\) to the isomorphism (3.12), and use (3.13) and (3.14) to obtain the desired canonical isomorphism (3.3); this concludes the proof of the claim.

3.6. The arithmetic tannakian group

In this section, we consider the situation over the finite field \(k\). Base change \(M \mapsto M_k\) gives a functor \(\text{P}_{\text{int}}(G) \to \text{P}(G)\). For a perverse sheaf \(M\) on \(G\), we define the set of unramified characters for \(M\) as \(\mathcal{X}(M) = \mathcal{X}^r(M)=\).

We denote by \(\text{Neg}_{\text{P}}^\text{ari}(G)\) (resp. \(\text{P}_{\text{int}}^\text{ari}(G)\)) the full subcategory of \(\text{P}_{\text{P}}(G)\) whose objects are the perverse sheaves \(M\) such that \(M_k\) is an object of \(\text{Neg}_{\text{P}}(G)\) (resp. \(\text{P}_{\text{int}}(G)\)). As in the geometric case, we find that \(\text{Neg}_{\text{P}}^\text{ari}(G)\) is a Serre subcategory of \(\text{P}_{\text{P}}^\text{ari}(G)\) and that the localization functor induces an equivalence from \(\text{P}_{\text{int}}^\text{ari}(G)\) to the quotient abelian category \(\text{P}_{\text{P}}^\text{ari}(G) = \text{P}_{\text{P}}(G)/\text{Neg}_{\text{P}}^\text{ari}(G)\).

Also similarly to the geometric case, the two convolution bifunctors on \(\text{P}_{\text{P}}(G)\) induce equivalent bifunctors on \(\text{P}_{\text{P}}^\text{ari}(G)\) (compare with Proposition 3.10). The categories \(\text{P}_{\text{P}}^\text{ari}(G)\) and \(\text{P}_{\text{int}}^\text{ari}(G)\)
are then rigid symmetric $\mathcal{Q}_f$-linear tensor categories, with unit object $1$ still the skyscraper sheaf at the unit of $G$, which again satisfies $\mathrm{End}(1) \simeq \mathcal{Q}_f$.

Let $M$ be a perverse sheaf on $G$. To distinguish between the arithmetic and geometric situations, we denote from now on by $(M)^{\text{ari}}$ (resp. $(M)^{\text{geo}}$) the subcategory of $\mathbf{P}_{\text{int}}(G) \simeq \mathbf{P}^{\text{ari}}(G)$ (resp. of $\mathbf{P}_{\text{int}}(G) \simeq \mathbf{P}(G)$) that is tensor-generated by (the image of) $M$ (resp. by $M_k$). Base change $N \mapsto N_k$ gives a functor from $(M)^{\text{ari}}$ to $(M)^{\text{geo}}$.

**Theorem 3.28.** Let $M$ be an object of $\mathbf{Perv}(G)$. The categories $(M)^{\text{ari}}$ and $(M)^{\text{geo}}$ are neutral $\mathcal{Q}_f$-linear tannakian categories. There exist algebraic groups $G^{\text{geo}}_M$ and $G^{\text{ari}}_M$ over $\mathcal{Q}_f$ such that $(M)^{\text{ari}}$ is equivalent to the category $\mathrm{Rep}_{\mathcal{Q}_f}(G^{\text{ari}}_M)$ and $(M)^{\text{geo}}$ is equivalent to the category $\mathrm{Rep}_{\mathcal{Q}_f}(G^{\text{geo}}_M)$.

Moreover, if $r$ is the tannakian dimension of $M$, then the objects $M$ and $M_k$ of $(M)^{\text{ari}}$ and $(M)^{\text{geo}}$, respectively, correspond to faithful representations of $G^{\text{ari}}_M$ and $G^{\text{geo}}_M$ in $\mathbf{GL}_r(\mathcal{Q}_f)$.

**Proof.** The case of $(M)^{\text{geo}}$ is dealt by Theorem 3.15 and Corollary 3.18. The case of $(M)^{\text{ari}}$ follows by the same argument because Proposition 3.16 also applies to $\mathbf{P}^{\text{ari}}(G)$.

The last assertion is a tautological consequence of the formalism. $\square$

**Remark 3.29.** We will call $G^{\text{ari}}_M$ the arithmetic tannakian group of $M$, and $G^{\text{geo}}_M$ its geometric tannakian group.

**Proposition 3.30.** Let $M$ be an object of $\mathbf{Perv}(G)$. The functor of base change to $\bar{k}$ is a tensor functor from $(M)^{\text{ari}}$ to $(M)^{\text{geo}}$ that induces a morphism $\varphi: G^{\text{geo}}_M \to G^{\text{ari}}_M$. This morphism is a closed immersion.

**Proof.** The first assertion is immediate, and it implies by the tannakian formalism the existence of the homomorphism $\varphi$. According to [30, Prop. 2.21 (b)], this morphism $\varphi$ is a closed immersion if and only if every object of $(M)^{\text{geo}}$ is isomorphic to a subquotient of an object in the essential image of the base-change functor.

Let $N$ be such an object of $(M)^{\text{geo}}$, viewed as an object of $\mathbf{P}_{\text{int}}(G)$. By definition of the category $\mathbf{P}(G)$, there exists a finite extension $k_n$ of $k$ in $\bar{k}$ such that $N$ is the base change to $\bar{k}$ of a perverse sheaf $N_1$ on $G_{k_n}$. Then $N$ is a subquotient of the base change of the perverse sheaf $f_{n*}N_1$ to $G_{\bar{k}}$, where $f_n: \mathrm{Spec}(k_n) \to \mathrm{Spec}(k)$ is the canonical morphism, hence the result. $\square$

From now on, we will identify the geometric tannakian group of a perverse sheaf $M$ on $G$ with its image in the arithmetic tannakian group.

We recall the convention from Section 1.11 concerning properties over $k$ and $\bar{k}$.

**Theorem 3.31.** Let $M$ be a perverse sheaf on $G$. Assume that $M$ is arithmetically semisimple and pure of weight zero. Let $r$ be the tannakian dimension of $M$.

1. The groups $G^{\text{ari}}_M$ and $G^{\text{geo}}_M$ are reductive subgroups of $\mathbf{GL}_r$.

2. Every object $N$ of $(M)^{\text{ari}}$ is arithmetically semisimple and pure of weight zero, and every object $N$ of $(M)^{\text{geo}}$ is semisimple.

**Proof.** Since any pure perverse sheaf on $G$ is geometrically semisimple by [6, Th. 5.3.8], the assertions for $(M)^{\text{geo}}$ follow. The same proof is also valid for $(M)^{\text{ari}}$, since $M$ is arithmetically semisimple, so that the group $G^{\text{ari}}_M$ is also reductive, and all objects of $(M)^{\text{ari}}$ are arithmetically semisimple.
We now prove the purity statement. Since $M$ is pure of weight zero, it follows from the description of $M_{\text{int}}$ in Remark 3.13 that the corresponding object of $P_{\text{int}}^\text{ari}(G)$ is also pure of weight zero, and similarly for its dual.

For any perverse sheaves $N_1$ and $N_2$ on $G$ that are pure of weight zero, the convolution $N_1 \ast \text{int} N_2$ is also pure of weight zero. Indeed, by Deligne’s Riemann Hypothesis [27, 3.3.1], the object $N_1 \ast \text{int} N_2$ is mixed of weights $\leq 0$. Hence, the quotient $N_1 \ast \text{int} N_2$ of $N_1 \ast \text{int} N_2$ is also mixed of weights $\leq 0$. Thanks to Lemma 1.15, the same applies to the Verdier dual $D(N_1 \ast \text{int} N_2)$, which implies the claim.

Hence, the property of being pure of weight zero is preserved by convolution, duality and taking subobjects. Thus we conclude that every object $N$ of $\langle M \rangle_{\text{int}}$ is pure of weight zero.

We now show that the tannakian groups coincide with those of Katz for the multiplicative group, and with monodromy groups of the Fourier transform for unipotent groups.

**Proposition 3.32.** Let $M$ be a perverse sheaf on $G$. Assume that $M$ is arithmetically semisimple and pure of weight zero.

1. If $G = \mathbb{G}_m$, then the arithmetic and geometric tannakian groups of $G$ coincide with those defined by Katz using category $\mathcal{P}$.
2. If $G$ is unipotent of dimension $d$, and $\psi$ is a fixed additive character used to define its Fourier transform, then there exists a dense open subset $U$ of the Serre dual $G^\vee$ such that $(\text{FT}_\psi M_{\text{int}})|_U$ is isomorphic to a lisse sheaf $\mathcal{F}$ on $U$, pure of weight $d$, placed in degree 0. The arithmetic and geometric tannakian groups of $M$ coincide with the arithmetic and geometric group of the lisse sheaf $\mathcal{F}$.

**Proof.** In the case of $\mathbb{G}_m$, the statement follows directly from Example 3.20 (1) (see also Section B.1 for the definition of $\mathcal{P}$).

Suppose then that $G$ is unipotent. To prove the first assertion, we may assume that $M$ is simple and non-negligible. Its Fourier transform is then a simple $d$-shifted perverse sheaf on the Serre dual $G^\vee$, pure of weight $d$, and with support equal to $G^\vee$ (since the object $M$ would be negligible if the support were smaller). Thus it is a single lisse sheaf, pure of weight $d$, on an open dense subset of $G^\vee$.

For the second part of (2), we note that by (the proof of) Theorem 3.25 for unipotent groups, the convolution product on $\langle M \rangle_{\text{int}}$ can be identified with the tensor product on the subcategory generated by $\mathcal{F}$ of the category of lisse sheaves on $U$. The result then follows. □

### 3.7. Frobenius conjugacy classes

We keep working over the finite field $k$ and use the same notation as in the previous subsection. For any finite extension $k_n$ of $k$, we denote by $\text{Fr}_{k_n}$ the geometric Frobenius automorphism of $k_n$.

For an object $M$ of $D^b_c(X)$, and a character $\chi \in \widehat{G}$, we denote by $\text{Fr}_{M,k_n}(\chi)$ the automorphism of the $\overline{\mathbb{Q}}_\ell$-vector space $H^0_c(G_{\overline{k}}, M_{\chi})$ induced by the action of $\text{Fr}_{k_n}$.

Let $r$ be the dimension of this space. If this automorphism is pure of weight zero, for instance if $M$ is pure of weight 0 and $\chi$ is weakly unramified for $M$, then there is a unique conjugacy class $\Theta_{M,k_n}(\chi)$ in the complex unitary group $U_r(C)$ containing the semisimple part of $i_0(\text{Fr}_{M,k_n}(\chi))$.

We call $\text{Fr}_{M,k_n}(\chi)$ the *Frobenius automorphism of $M$ associated to $\chi$ over $k_n$* and $\Theta_{M,k_n}(\chi)$ the *unitary Frobenius conjugacy class of $M$ associated to $\chi$ over $k_n$*.

Suppose now that $M$ is an arithmetically semisimple perverse sheaf on $G$. 

64
Let \( n \geq 1 \) and let \( \chi \in \hat{G}(k_n) \) be an unramified character for \( M \), so that the functor \( \omega_\chi : N \mapsto H^0(G_k, N_\chi) \) is a fiber functor on the tannakian category \( (M)^\text{ari} \). For any object \( N \) of \( (M)^\text{ari} \), the Frobenius automorphism \( \text{Fr}_{k_n} \) now induces an automorphism of \( \omega_\chi(N) \), and thus defines an automorphism of the fiber functor \( \omega_\chi \). By the tannakian formalism, this corresponds to a unique conjugacy class in \( G^\text{ari}_M(\overline{Q}) \). We denote by \( \text{Fr}_{M,k_n}(\chi) \) the corresponding conjugacy class of \( G^\text{ari}_M(C) \), and call it the Frobenius conjugacy class of \( M \) associated to \( \chi \) over \( k_n \).

Suppose furthermore that \( M \) is pure of weight zero. Let \( K_M \) be a maximal compact subgroup of the reductive group \( G^\text{ari}_M(C) \). Since all objects of \( (M)^\text{ari} \) are pure of weight zero (by Theorem 3.31), the Peter–Weyl Theorem implies that the semisimple part of \( \text{Fr}_{M,k_n}(\chi) \) intersects \( K_M \) in a unique conjugacy class, which is denoted \( \Theta_{M,k_n}(\chi) \), and is called the unitary Frobenius conjugacy class of \( M \) associated to \( \chi \).

For an unramified character \( \chi \), the space \( \omega_\chi(M) \) has dimension \( r \), the tannakian dimension of \( M \), and the conjugacy class of \( \text{Fr}_{M,k_n}(\chi) \) in the automorphism group of \( H^0_c(G_k, M_\chi) \) coincides with that of \( \Theta_{M,k_n}(\chi) \), and similarly for \( \Theta_{M,k_n}(\chi) \).

When \( k_n = k \), we will sometimes use simply the notation \( \text{Fr}_M(\chi), \Theta_M(\chi), \Phi_M(\chi) \).

We have the following important consequences of the formalism.

**Lemma 3.33.** Let \( M \) be an arithmetically semisimple perverse sheaf on \( G \) that is pure of weight zero and of tannakian dimension \( r \geq 0 \).

1. Let \( \chi \in \mathcal{X}_w(M)(k) \) be a weakly unramified character for \( M \). For any integer \( n \geq 1 \), we have
   \[
   \text{Tr}(\Theta_{M,k_n}(\chi)) = \text{Tr}(\Theta_M(\chi)^n) = \sum_{x \in G(k_n)} \chi(N_{k_n/k}(x))t_M(x;k_n),
   \]
   where \( t_M \) is the trace function of \( M \) and the trace on the left is that on \( GL_r \).

2. Let \( \chi \in \mathcal{X}(M)(k) \) be an unramified character. Let \( g \) be an algebraic \( \overline{Q}_\ell \)-representation of \( G^\text{ari}_M \) and denote by \( g(M) \) the corresponding object of \( (M)^\text{ari} \). The character \( \chi \) is unramified for \( g(M) \) and
   \[
   \text{Tr}(g(\text{Fr}_M(\chi))) = \text{Tr}(\text{Fr}_k \mid H^0_c(G_k, g(M)_\chi)).
   \]

**Proof.** (1) By definition, we have
   \[
   \text{Tr}(\Theta_M(\chi)^n) = \text{Tr}(\text{Fr}_M(\chi)^n) = \text{Tr}(\text{Fr}_k^n \mid H^0_c(G_k, M_\chi)).
   \]
   Since \( \chi \) is weakly unramified, we have \( H^i_c(G_k, M_\chi) = 0 \) for all \( i \neq 0 \) and \( H^0_c(G_k, M_\chi) = H^0_c(G_k, M_\chi) \), so that we can write
   \[
   \text{Tr}(\Theta_M(\chi)^n) = \sum_{i \in \mathbb{Z}} (-1)^i \text{Tr}(\text{Fr}_k^n \mid H^i_c(G_k, M_\chi)) = \sum_{x \in G(k)} \chi(N_{k_n/k}(x))t_M(x;k_n),
   \]
   by the trace formula.

   (2) The fact that \( \chi \) is unramified for \( g(M) \) follows from the definition and Proposition 1.30, and the formula follows then from the definition of the Frobenius conjugacy class of \( \chi \) for \( g(M) \).

**3.8. Frobenius-unramified characters**

Because weakly unramified characters do not always give rise to fiber functors, and moreover we do not always know if there exist sufficiently many (if any) unramified characters, we introduce an intermediate notion.

65
**Definition 3.34 (Frobenius-unramified characters).** Let \( M \) be an object of \( \mathbf{Perv}(G) \) which is arithmetically semisimple and pure of weight zero, of tannakian dimension \( r \). Let \( \varphi \) be a representation of \( \mathrm{GL}_r \) and let \( N \) be the object of \( \langle M \rangle_{\mathrm{ari}} \) corresponding to the restriction of \( \varphi \) to \( \mathrm{G}_M \). Let \( n \geq 1 \) and let \( \chi \in \mathcal{F}_{\otimes}(M)(k_n) \) be a weakly unramified character for \( M \). We say that \( \chi \) is **Frobenius-unramified for \( \varphi \)** if \( \chi \) is weakly unramified for \( N \) and if the formula

\[
\text{Tr}(\varphi(\Theta_{M,k_n}(\chi))v) = \text{Tr}(\text{Fr}_{k_n} | H^0_c(G_k,N\chi))
\]

holds for all integers \( v \geq 1 \), or equivalently if

\[
\det(1 - \varphi(\Theta_{M,k_n}(\chi))T) = \det(1 - T \text{Fr}_{k_n} | H^0_c(G_k,N\chi)).
\]

The disjoint union over \( n \) of the set of Frobenius-unramified characters is denoted \( \mathcal{F}_F(\varphi) \).

**Remark 3.35.** (1) The key point is that since \( \varphi \) is a representation of \( \mathrm{GL}_r \), we can consider the conjugacy class of \( \varphi(\text{Fr}_{M,k_n}(\chi)) \) (in \( \mathrm{GL}(V) \), where \( \varphi \) is a representation on \( V \)); a priori, this is not possible for a representation of \( \mathrm{G}_M \), unless we know that the conjugacy class of the Frobenius automorphism of \( H^0_c(G_k,M\chi) \) happens to be conjugate to some element of the arithmetic tannakian group.

(2) We will also sometimes write \( \mathcal{F}_F(\varphi) = \mathcal{F}_F(N) \), although this set depends on \( M \), since we view \( N \) as an object of \( \langle M \rangle_{\mathrm{ari}} \). When confusion might arise, we may also write \( \mathcal{F}_F(N)_M \).

Any unramified character for \( M \) is Frobenius-unramified for all objects of \( \langle M \rangle_{\mathrm{ari}} \) (see Lemma 3.33, (2)). But in contrast to unramified characters, we can prove in all cases that the set of Frobenius-unramified characters is generic.

**Proposition 3.36.** Let \( M \) be an object of \( \mathbf{Perv}(G) \) which is arithmetically semisimple and pure of weight zero and of tannakian dimension \( r \geq 0 \). For any representation \( \varphi \) of \( \mathrm{GL}_r \), the set \( \mathcal{F}_F(\varphi) \) is generic.

**Proof.** We first suppose that there exist non-negative integers \( m \) and \( l \) such that \( N \) is the object \( M_{m,l} = M^{\ast m} \ast \int (M^\vee)^{\ast l} \) (in other words, we assume that \( \varphi = \text{Std}^m \otimes (\text{Std}^\vee)^l \), where \( \text{Std} \) is the “tautological” identity representation of \( \mathrm{GL}_r \)).

Let \( C \) be the cone of the canonical morphism \( M^{\ast m} \ast_!(M^\vee)^{\ast l} \rightarrow M^{\ast m} \ast_*(M^\vee)^{\ast l} \). By Lemma 3.8, the object \( C \) belongs to \( \sigma_D(\mathcal{O}) \), and hence for \( \chi \) in the generic set \( \mathcal{M}(C) \), the equalities

\[
H^i_c(G_k,C\chi) = H^i(G_k,C\chi) = 0
\]

hold for every \( i \in \mathbb{Z} \).

For \( \chi \in \mathcal{M}(C) \), we have canonical isomorphisms

\[
H^i_c(G_k,(M^{\ast m} \ast_!(M^\vee)^{\ast l})\chi) \simeq H^i_c(G_k,(M^{\ast m} \ast_*(M^\vee)^{\ast l})\chi)
\]

and

\[
H^*(G_k,(M^{\ast m} \ast_!(M^\vee)^{\ast l})\chi) \simeq H^*(G_k,(M^{\ast m} \ast_*(M^\vee)^{\ast l})\chi).
\]

By Remark 3.13, there is a generic set \( U \subset \widehat{G} \) such that for \( \chi \in U \), we have canonical isomorphisms

\[
H^i_c(G_k,(M_{m,l})\chi) \simeq H^i_c(G_k,(M^{\ast m} \ast_!(M^\vee)^{\ast l})\chi)
\]

and

\[
H^*(G_k,(M_{m,l})\chi) \simeq H^*(G_k,(M^{\ast m} \ast_!(M^\vee)^{\ast l})\chi).
\]
We now define $\mathcal{X}_{m,l} = \mathcal{X}_{w}(M) \cap \mathcal{N}(C) \cap U$; this is a generic set, and we will show that it satisfies the stated conditions for the object $M_{m,l}$.

Let $n \geq 1$ and let $\chi \in \mathcal{X}_{m,l}(k_n)$. By the Künneth isomorphisms of Lemma 1.15 and the fact that $\chi$ is weakly unramified for $M$ (and therefore also for $M^v$), we have canonical isomorphisms

\begin{align}
(3.19) \quad H^*_c(G_k, (M^\ast_{+} \ast_1 (M^v)^{\ast_1})_{\chi}) &\simeq H^0_c(G_k, M_\chi)^{\otimes m} \otimes (H^0_c(G_k, M_\chi)^{\ast} \otimes H^0_c(G_k, M_\chi^v)^{\ast})^\otimes \\
(3.20) \quad H^v(G_k, (M^\ast_{+} \ast_1 (M^v)^{\ast_1})_{\chi}) &\simeq H^0(G_k, M_\chi)^{\otimes m} \otimes (H^0(G_k, M_\chi^v)^{\ast})^\otimes.
\end{align}

The canonical isomorphism $H^0_c(G_k, M) \simeq H^0(G_k, M_\chi)$ now implies an isomorphism between the objects in (3.19) and (3.20).

Combining this isomorphism with the ones of (3.15), (3.16), (3.17) and (3.18) proves that $\chi$ is weakly unramified for $M_{m,l}$ and gives a canonical isomorphism

\begin{align}
(3.21) \quad H^0(G_k, M_\chi)^{\otimes m} \otimes (H^0_c(G_k, M_\chi^v)^{\ast})^\otimes \simeq H^0_c(G_k, (M_{m,l})_\chi).
\end{align}

from which it follows that

\begin{align}
(3.22) \quad \text{Tr}(\text{Fr}_{M_{m,l}, k_n}(\chi^v)) = \text{Tr}(\text{Fr}_{M, k_n}(\chi^v)^{m} \bar{\text{Tr}}(\text{Fr}_{M, k_n}(\chi)^v)^{l}),
\end{align}

for all $v \geq 1$, which is the desired conclusion.

In the case of a general object $N$, we appeal to Proposition 1.30 to express $N$ as a finite direct sum of subobjects of the form $M_{m,l}$ for suitable values of $m$ and $l$, and we apply the result for these.

\begin{quote}
COROLLARY 3.37. Let $M$ be an object of $\text{Perv}(G)$ which is arithmetically semisimple and pure of weight zero and of tannakian dimension $r \geq 0$. If the group $G_{M}^{\text{ari}}$ is finite, then $M$ is generically unramified.
\end{quote}

\begin{proof}
The fact that the tannakian group is finite implies that any object of $\langle M \rangle^{\text{ari}}$ is a subobject of a direct sum of copies of a single object $N = M^{\ast_{\text{int}}} \ast_{\text{int}} (M^v)^{\ast_{\text{int}}}$ for some (fixed) integers $m$ and $l$ (see [30, Prop. 2.20 (a)]). Any Frobenius-unramified character for $N$ is then an unramified character for $M$.
\end{proof}

\section{3.9. Group-theoretic properties}

We continue with the notation of the previous sections.

The following basic proposition establishes the relation between the geometric and arithmetic tannakian groups.

\begin{proposition}
Let $M$ be a geometrically semisimple object of $\text{Perv}(G)$. The geometric tannakian group $G_{M}^{\text{geo}}$ is a normal subgroup of the arithmetic tannakian group $G_{M}^{\text{ari}}$.
\end{proposition}

\begin{proof}
The proof is identical with that of [68, Lemma 6.1].
\end{proof}

\begin{proposition}
Let $M$ be an arithmetically semisimple object of $\text{Perv}(G)$. Assume that $M$ is pure of weight zero.

\begin{enumerate}
\item The quotient $G_{M}^{\text{ari}}/G_{M}^{\text{geo}}$ is of multiplicative type.
\item Let $V$ be a geometrically trivial object of $\langle M \rangle^{\text{ari}}$ which corresponds to a faithful representation of the group $G_{M}^{\text{ari}}/G_{M}^{\text{geo}}$. Any character $\chi \in \hat{G}$ is unramified for $V$, and the class $\xi$ of the Frobenius conjugacy class of any such character is independent of $\chi$ and generates a Zariski-dense subgroup of $G_{M}^{\text{ari}}/G_{M}^{\text{geo}}$.
\end{enumerate}
\end{proposition}
(3) For any $n \geq 1$ and any character $\chi \in \hat{G}(k_n)$ unramified for $M$, the image in $G^{\text{uni}}_M/G^{\text{geo}}_M$ of the Frobenius conjugacy class $\text{Fr}_{M,k}(\chi)$ is equal to $\xi^n$.

**Proof.** This follows by the same arguments as in [68, Lemma 7.1] (checking first that, using the structure of geometrically trivial objects as direct sums of $\alpha^{\text{deg}} \otimes \delta_1$ for suitable $\alpha$, it is indeed straightforward that all characters are unramified for such objects). □

We will also use the following result in Chapter 10.

**Proposition 3.40.** Let $G_1$ and $G_2$ be connected commutative algebraic groups over $k$ and let $p: G_1 \to G_2$ be a morphism of algebraic groups. Let $M$ be a perverse sheaf on $G_1$ which is arithmetically semisimple and pure of weight zero.

Let $\chi_1 \in \hat{G}_1(k)$ be a character such that we have $Rp(M_{\chi_1}) = Rp_*(M_{\chi_1})$. Assume further that $N = Rp(M_{\chi})$ is perverse and arithmetically semisimple.

(1) The object $N$ is pure of weight zero.
(2) Let $n \geq 1$ and let $\chi \in \mathcal{X}_m(N)(k_n)$ be a character such that $\chi_1 \cdot (\chi \circ p)$ is weakly unramified for $M$. Then the conjugacy classes $\Theta_{M,k_n}(\chi_1 \cdot (\chi \circ p))$ and $\Theta_{N,k_n}(\chi)$ satisfy

$$\det(1 - T\Theta_{M,k_n}(\chi_1 \cdot (\chi \circ p))) = \det(1 - T\Theta_{N,k_n}(\chi)) \in \mathbb{C}[T]$$

and in particular

$$\det(\Theta_{M,k_n}(\chi_1 \cdot (\chi \circ p))) = \det(\Theta_{N,k_n}(\chi)).$$

**Proof.** It suffices to consider the case where $\chi \in \hat{G}(k)$. For any $n \geq 1$, the exponential sums

$$S_n = \sum_{x \in G_1(k_n)} t_M(x; k_n)(\chi_1 \cdot (\chi \circ p))(N_{k_n/k}(x))$$

$$S'_n = \sum_{y \in G_2(k_n)} t_N(y; k_n)\chi(N_{k_n/k}(y))$$

are equal by the trace formula. Hence, the corresponding L-functions

$$\exp\left(\sum_{n \geq 1} S_n \frac{T^n}{n}\right), \quad \exp\left(\sum_{n \geq 1} S'_n \frac{T^n}{n}\right)$$

are also equal. But these L-functions coincide with the (reversed) characteristic polynomials of the conjugacy classes $\Theta_{M,k}(\chi_1 \cdot (\chi \circ p))$ and $\Theta_{N,k}(\chi)$, by Lemma 3.33 (1), hence the result. □

**Remark 3.41.** If the morphism $p: G_1 \to G_2$ is affine, then the condition $Rp(M_{\chi_1}) = Rp_*(M_{\chi_1})$ implies that $N$ is perverse.

We will give an application when the group $G_2$ is the multiplicative group. For this we need a lemma.

**Lemma 3.42.** Let $N$ be a simple perverse sheaf on $G_m$ over $k$ which is an object of the category $\mathcal{P}^{\text{uni}}_{\text{int}}(G_m)$. Assume that $N$ is pure of weight 0 and of tannakian dimension 1. Suppose that there exists an integer $d \geq 1$ and a finite set $\mathcal{V} \subset \hat{G}_m$ such that for all $n \geq 1$ and for $\chi \in \hat{G}_m(k_n) - \mathcal{V}(k_n)$, the determinant $\det(\Theta_{N,k_n}(\chi))^d$ depends only on $n$. Then $N$ is geometrically of finite order.

**Proof.** If $N$ is not geometrically of finite order, then the perverse sheaf $N$ is a hypergeometric sheaf of generic rank at least 1 (see Section B.4 and Theorem B.4 for reminders of the definition of hypergeometric sheaves and for this result, due to Katz). But these hypergeometric sheaves do not have the indicated property, e.g. because the $\Theta_{N,k_n}(\chi)$ become equidistributed in $S^1$ as $\chi$ varies.
among unramified characters in $\hat{G}_m(k_n)$ (see Theorem B.4, (3) and [68, Th. 7.2] or Theorem 4.11).

PROPOSITION 3.43. Let $G$ be a connected commutative algebraic group over $k$ and let $p: G \to G_m$ be a non-trivial morphism of algebraic groups. Let $M$ be a perverse sheaf on $G$ which is arithmetically semisimple and pure of weight zero.

Let $\chi_1 \in \hat{G}(k)$ be a character such that the equality $R\pi(M_{\chi_1}) = Rp_*(M_{\chi_1})$ holds. Assume further that the complex $N = Rp! (M_{\chi_1})$ is a perverse sheaf on $G_m$ and is arithmetically semisimple. It is then pure of weight zero.

Suppose that the set of $\chi \in \hat{G}_m$ such that $\chi_1(\chi \circ p)$ is unramified for the object $\text{det}(M)$ is generic, and that the tannakian determinant of $N$ is arithmetically (resp. geometrically) of infinite order. Then the tannakian determinant of $M$ has infinite order.

PROOF. We begin by proving that the determinant is arithmetically of infinite order in both cases. Let $n \geq 1$ and let $\chi \in \hat{G}_m(k_n)$ be a character such that $\chi_1(\chi \circ p)$ is unramified for the object $\text{det}(M)$. We then have

$$\Theta_{\text{det}(M),k_n}(\chi) = \text{det} \left( \Theta_{M,k_n}(\chi_1(\chi \circ p)) \right) = \text{det} \left( \Theta_{N,k_n}(\chi) \right)$$

by Proposition 3.40. By assumption this is valid for all but finitely many $\chi \in \hat{G}_m$, and moreover $N$ has determinant which is arithmetically of infinite order, so that the arithmetic tannakian group of $\text{det}(M)$ must be infinite.

It remains to deduce that the geometric tannakian determinant of $M$ has infinite order if the same property holds for $N$. If not, then $\text{det}(M)^d$ would be geometrically trivial for some integer $d \geq 1$. In this case, for any $n \geq 1$ and any character $\chi \in \hat{G}(k_n)$ which is Frobenius-unramified for $\text{det}$, the determinant $\text{det}(\Theta_{M,k_n}(\chi))^d$ only depends on $n$ (see Proposition 3.39, (2)). By (3.23) and Lemma 3.42, the tannakian determinant of $N$ (which is an object of tannakian dimension 1 on $G_m$) is geometrically of finite order, which contradicts the assumption.

REMARK 3.44. If $G = T \times G_m$ for some torus $T$ and $p$ is the projection on $G_m$ then, according to Theorem 2.11 applied to $p$ and $M$, the assumption that $R\pi M_{\chi_1} = R\pi M_{\chi_1}$ and that this complex is a perverse sheaf is true for all $\chi_1$ outside of a finite union of tacs of $T$. Moreover, by varying $\chi_1$, we can always find such a character for which $\chi_1(\chi \circ p)$ is unramified for generic $\chi$, since $M$ is generically unramified by Theorem 3.25.

Using further work of Katz, we can give a sufficient criterion to apply this proposition.

COROLLARY 3.45. Let $G$ be a connected commutative algebraic group over $k$ and let $p: G \to G_m$ be a non-trivial morphism of algebraic groups. Let $M$ be a perverse sheaf on $G$ which is arithmetically semisimple and pure of weight zero.

Let $\chi_1 \in \hat{G}(k)$ be a character such that $R\pi(M_{\chi_1}) = Rp_*(M_{\chi_1})$. Assume that this object $N = Rp! (M_{\chi_1})$ is a perverse sheaf on $G_m$, which is arithmetically semisimple and of the form $\mathcal{F}[1]$ for some middle extension sheaf $\mathcal{F}$ (see Example A.12 for the definition of middle extension sheaves). Let

$$(e_1, \ldots, e_l), \quad (f_1, \ldots, f_m)$$

the size of the unipotent Jordan blocks in the tame monodromy representation of $\mathcal{F}$ at 0 and $\infty$ respectively.

Suppose that the set of $\chi \in \hat{G}_m$ such that $\chi_1(\chi \circ p)$ is unramified for the object $\text{det}(M)$ is generic.
If we have
\[ \sum_i e_i - \sum_j f_j \neq 0, \]
then the tannakian determinant of \( M \) is geometrically of infinite order.

Proof. According to the previous proposition, it suffices to show that the tannakian determinant of \( N \) is geometrically of infinite order. By [68, Th. 16.1], the condition implies that the determinant of the Frobenius action on Deligne’s fiber functor \( \omega_{\text{Del}}(N) \) is not unitary (see Section B.2 for the definition of this functor), and the result follows from Katz’s classification of objects of tannakian dimension 1 on \( G_m \) (Theorem B.4). \( \square \)
CHAPTER 4

Equidistribution theorems

4.1. Equidistribution on average

Along with the classical form of equidistribution that goes back in principle to Weyl and appears in Deligne’s equidistribution theorem, we will use a useful variant that allows us to avoid the assumption that the geometric and the arithmetic tannakian groups are equal, at the cost of getting slightly weaker statements.

**Definition 4.1.** Let $X$ be a locally compact topological space and let $\mu$ be a Borel probability measure on $X$. Let $(Y_n, \Theta_n)_{n \geq 1}$ be a sequence of pairs of finite sets $Y_n$ and maps $\Theta_n: Y_n \to X$.

1. We say that $(Y_n, \Theta_n)$, or simply $(Y_n)$ when the maps $\Theta_n$ are clear from the context, becomes $\mu$-equidistributed on average as $n \to \infty$ if the sets $Y_n$ are non-empty for all large enough $n$ and if the sequence of probability measures
   \[
   \mu_N = \frac{1}{N'} \sum_{1 \leq n \leq N, Y_n \neq \emptyset} \frac{1}{|Y_n|} \sum_{y \in Y_n} \delta_{\Theta_n(y)}, \quad N' = |\{n \leq N \mid Y_n \neq \emptyset\}|,
   \]
   defined on $X$ for large enough $N$, converges weakly to $\mu$ as $N$ goes to infinity, i.e., for any bounded continuous function $f: X \to \mathbb{C}$, the following holds:
   \[
   \lim_{N \to +\infty} \frac{1}{N'} \sum_{1 \leq n \leq N, Y_n \neq \emptyset} \frac{1}{|Y_n|} \sum_{y \in Y_n} f(\Theta_n(y)) = \int_X f \, d\mu.
   \]

2. The sequence $(Y_n, \Theta_n)$, or simply $(Y_n)$, becomes $\mu$-equidistributed as $n \to \infty$ if the sets $Y_n$ are non-empty for all large enough $n$ and if the sequence of probability measures
   \[
   \tilde{\mu}_n = \frac{1}{|Y_n|} \sum_{y \in Y_n} \delta_{\Theta_n(y)},
   \]
   defined on $X$ for large enough $n$, converges weakly to $\mu$ as $n$ goes to infinity, i.e., for any bounded continuous function $f: X \to \mathbb{C}$, the following holds:
   \[
   \lim_{n \to +\infty} \frac{1}{|Y_n|} \sum_{y \in Y_n} f(\Theta_n(y)) = \int_X f \, d\mu.
   \]

**Remark 4.2.**

1. In practice, since $N' \sim N$ as $N \to +\infty$, we will sometimes not distinguish between $N$ and $N'$, and use the convention that those terms for which $Y_n$ is empty are omitted from the sum over $n$ when discussing equidistribution on average.

2. Since convergence of a sequence $(x_n)$ of complex numbers implies that of its Cesàro means $(N^{-1} \sum_{1 \leq n \leq N} x_n)$, with the same limit, equidistribution implies equidistribution on average.
4.2. The basic estimate

We state here a preliminary estimate that will be the key analytic step in the proof of our equidistribution results, including Theorem 2.

We denote as usual by $k$ a finite field with algebraic closure $\bar{k}$, and by $k_n$ the extension of $k$ of degree $n$ in $\bar{k}$. We fix a prime $\ell$ distinct from the characteristic of $k$.

**Proposition 4.3.** Let $G$ be a commutative connected algebraic group over $k$. Let $M$ be an $\ell$-adic perverse sheaf on $G$ that is arithmetically semisimple and pure of weight zero, and of tannakian dimension $r$. Let $N$ be an object of $(\mathbb{M})^\text{ari}$.

For all $n \geq 1$ such that $\mathcal{X}_F(N)(k_n)$ is not empty, the following estimate holds:

\[
(4.3) \quad \frac{1}{|\mathcal{X}_F(N)(k_n)|} \sum_{\chi \in \mathcal{X}_F(N)(k_n)} \text{Tr}(\text{Fr}_{k_n} \mid H^0_c(G_{\bar{k}}, N_{\chi})) = t_N(e; k_n) + O(|k_n|^{-1/2}).
\]

**Proof.** Let $d$ denote the dimension of $G$, and put $\mathcal{X} = \mathcal{X}_F(N)$. For each non-zero integer $i$, consider the subset

$$\mathcal{X}_i = \{ \chi \in \hat{G} \mid H^i_c(G_{\bar{k}}, N_{\chi}) \neq 0 \}$$

consisting of those characters $\chi$ such that $N_{\chi}$ has non-trivial cohomology with compact support in degree $i$. Then the left-hand side of (4.3) is equal to

\[
\frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{X}(k_n)} \text{Tr}(\text{Fr}_{k_n} \mid H^0_c(G_{\bar{k}}, N_{\chi})) = \frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{G}(k_n)} \sum_{|i| \leq d} (-1)^i \text{Tr}(\text{Fr}_{k_n} \mid H^i_c(G_{\bar{k}}, N_{\chi}))
\]

\[
- \frac{1}{|\mathcal{X}(k_n)|} \sum_{0 < |i| \leq d} (-1)^i \sum_{\chi \in \mathcal{X}_i(k_n)} \text{Tr}(\text{Fr}_{k_n} \mid H^i_c(G_{\bar{k}}, N_{\chi}))
\]

\[
- \frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{G}(k_n) - \mathcal{X}(k_n)} \text{Tr}(\text{Fr}_{k_n} \mid H^0_c(G_{\bar{k}}, N_{\chi})).
\]

By the Grothendieck–Lefschetz trace formula (see (A.4)), the equality

\[
\sum_{|i| \leq d} (-1)^i \text{Tr}(\text{Fr}_{k_n} \mid H^i_c(G_{\bar{k}}, N_{\chi})) = \sum_{x \in \mathcal{G}(k_n)} \chi(x) \text{Tr}(\text{Fr}_{k_n,x} \mid N)
\]

holds for any character $\chi$. Combined with the orthogonality of characters of $G(k_n)$, this shows that the first summand in (4.4) is equal to

\[
\frac{|\mathcal{G}(k_n)|}{|\mathcal{X}(k_n)|} \text{Tr}(\text{Fr}_{k_n,e} \mid N) = t_N(e; k_n) + O(|k_n|^{-1})
\]

since the set $\mathcal{X}$ is generic, so that the estimate $\frac{|\mathcal{G}(k_n)|}{|\mathcal{X}(k_n)|} = 1 + O(|k_n|^{-1})$ holds.

We now turn to bounding the second and the third summands in the right-hand side of (4.4).

Since $M$ is pure of weight zero, the same holds for $N$ and $N_{\chi}$ by Theorem 3.31. It then follows from Deligne’s Riemann Hypothesis (see Theorem A.19) that $H^i_c(G_{\bar{k}}, N_{\chi})$ is mixed of weights $\leq i$ for any $i$, in particular the eigenvalues of $\text{Fr}_{k_n}$ acting on this space have modulus at most $|k_n|i/2$. Moreover, using (1.1) and Theorem 1.5(2), we get

\[
h^i_c(G_{\bar{k}}, N_{\chi}) \leq c_u(N_{\chi}) \ll c_u(N)c_u(\mathcal{X}_\chi) \ll c_u(N)
\]
since the complexity \( c_u(\mathcal{L}_\chi) \) is bounded independently of \( \chi \) by Proposition 1.18. Finally, the Stratified Vanishing Theorem 2.3 applied to \( N \) gives the estimate

\[
|\mathcal{A}(k_n)| \ll |k_n|^{d-1}.
\]

(4.5) We conclude that the second term can be bounded by

\[
\frac{1}{|\mathcal{X}(k_n)|} \sum_{0<i\leq d} \sum_{\chi \in \mathcal{A}(k_n)} h^{i}_{\chi}(G_k, N_{\chi})|k_n|^{i/2} \leq \frac{1}{|\mathcal{X}(k_n)|} \sum_{0<i\leq d} \sum_{\chi \in \mathcal{A}(k_n)} |k_n|^{i/2} \leq \frac{1}{|\mathcal{X}(k_n)|} \sum_{0<i\leq d} |k_n|^{d-i/2} \ll |k_n|^{d-1/2}.
\]

(4.6) Thanks to the estimate \( |\mathcal{X}(k_n)| = |k_n|^d + O(|k_n|^{d-1}) \), the last term is \( \ll |k_n|^{-1/2} \) and tends to 0 as \( n \to +\infty \).

Finally, the third term satisfies

\[
\frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{G}(k_n)} \text{Tr}(\text{Fr}_{k_n} | H^{0}_{\chi}(G_k, N_{\chi})) \ll \frac{|\mathcal{G}(k_n)| - |\mathcal{X}(k_n)|}{|\mathcal{X}(k_n)|} \ll \frac{1}{|k_n|}
\]

(4.7) since \( H^{0}_{\chi}(G_k, N_{\chi}) \) is mixed of weights \( \leq 0 \) and has dimension bounded for all \( \chi \), and the set \( \mathcal{X} \) is generic. This finishes the proof. \( \square \)

### 4.3. Equidistribution for characteristic polynomials

Let \( k \) be a finite field, with an algebraic closure \( \bar{k} \), and let \( G \) be a connected commutative algebraic group over \( k \). Let \( \ell \) be a prime number distinct from the characteristic of \( k \).

Our most general equidistribution result concerns the characteristic polynomials of the unitary Frobenius conjugacy classes for weakly unramified characters. Equivalently, this is about the conjugacy classes in the ambient unitary group.

**Theorem 4.4.** Let \( M \) be an \( \ell \)-adic perverse sheaf on \( G \) that is arithmetically semisimple and pure of weight zero. Let \( r \geq 0 \) be the tannakian dimension of \( M \). Let \( K \subset G_{\mathbb{M}^r}(\mathbb{C}) \subset \text{GL}_r(\mathbb{C}) \) be a maximal compact subgroup of the arithmetic tannakian group of \( M \), and denote by \( \nu_{cp} \) the measure on the set \( U_r(\mathbb{C})^\sharp \) of conjugacy classes in the unitary group which is the direct image of the Haar probability measure \( \mu \) on \( K \) by the natural map \( K \to U_r(\mathbb{C})^\sharp \). Then the families of unitary conjugacy classes \( \left( \Theta_{M,k_n}(\chi) \right)_{\chi \in \mathcal{X}_w(M)(k_n)} \) become \( \nu_{cp} \)-equidistributed on average in \( U_r(\mathbb{C})^\sharp \) as \( n \to +\infty \).

**Remark 4.5.** (1) To be precise, in terms of Definition 4.1, we consider the equidistribution on average of pairs \( (\mathcal{X}_w(M)(k_n), \Theta_n) \) with \( \Theta_n(\chi) = \Theta_{M,k_n}(\chi) \).

(2) The set \( U_r(\mathbb{C})^\sharp \) can be identified with the set of characteristic polynomials of unitary matrices of size \( r \), or equivalently with the quotient topological space \( (S_1)^r/\mathcal{G}_r \) (by mapping a matrix to the set of eigenvalues, with multiplicity) so the statement means that the characteristic polynomials of the Frobenius automorphisms for weakly unramified characters tend to be distributed like the characteristic polynomials of random elements of \( K \).

**Proof.** Let \( \mathcal{X} = \mathcal{X}_w(M) \). It suffices to check the equality (4.1) for \( f \) taken in a set of continuous functions on \( U_r(\mathbb{C})^\sharp \) that span a dense subset of the Banach space \( \mathcal{C}(U_r(\mathbb{C})^\sharp) \) of all continuous complex-valued functions on \( U_r(\mathbb{C})^\sharp \) (since probability measures on \( U_r(\mathbb{C})^\sharp \) are continuous functionals on \( \mathcal{C}(U_r(\mathbb{C})^\sharp) \) by the Riesz representation theorem). Thanks to the Peter–Weyl Theorem,
it suffices to prove the equality
\[
\lim_{N \to +\infty} \frac{1}{N} \sum_{1 \leq n \leq N} \frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{X}(k_n)} \text{Tr}(\rho(\Theta_{M,k_n}(\chi))) = \int_K \text{Tr}(\rho(g))d\mu(g)
\]
for any irreducible unitary representation \(\rho\) of \(U_r(\mathbb{C})\). In fact, we will prove this for any unitary representation \(\rho\), not necessarily irreducible.

By the Peter–Weyl Theorem again, the right-hand side is the multiplicity of the trivial representation in the representation of \(G^\text{ari}\) that corresponds to the restriction of \(\rho\) to \(K\). We denote by \(N = \rho(M)\) the object of \(\langle M \rangle^\text{ari}\) that corresponds to this restriction of \(\rho\).

Let \(\mathcal{X}_N = \mathcal{X}_F(N)\) be the set of Frobenius-unramified characters for \(N\). We have
\[
\lim_{N \to +\infty} \frac{1}{N} \sum_{1 \leq n \leq N} \frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{X}(k_n)} \text{Tr}(\rho(\Theta_{M,k_n}(\chi))) = 0,
\]
since \(\mathcal{X}_N\) is generic (by Proposition 3.36) and the upper-bound
\[
|\text{Tr}(\rho(\Theta_{M,k_n}(\chi)))| \leq \dim(\rho)
\]
holds for all \(\chi \in \mathcal{X}(k_n)\).

By the definition of Frobenius-unramified characters, we have
\[
\frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{X}(k_n)} \text{Tr}(\rho(\Theta_{M,k_n}(\chi))) = \frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{X}(k_n)} \text{Tr}(\text{Fr}_{k_n}^e | H^0_c(G_{k_n}, \mathcal{N}_\chi))
\]
for \(n \geq 1\). Since \(\mathcal{X}\) and \(\mathcal{X}_N\) are both generic, we have \(|\mathcal{X}(k_n)|/|\mathcal{X}_N(k_n)| = 1 + O(1/|k_n|)\). By Proposition 4.3, we deduce that
\[
\frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{X}(k_n)} \text{Tr}(\rho(\Theta_{M,k_n}(\chi))) = t_N(e; k_n) + O(|k_n|^{-1/2}),
\]
where \(e\) is the identity of \(G\).

We decompose the semisimple perverse sheaf \(N\) as a direct sum
\[
N = \bigoplus_{r \geq 0} \bigoplus_{i \in I(r)} N_{r,i}
\]
of pairwise non-isomorphic arithmetically simple perverse sheaves \(N_{r,i}\) of support of dimension \(r\). For \(r \geq 1\), we get the pointwise bound
\[
t_{N_{r,i}}(e; k_n) \ll \frac{1}{\sqrt{|k_n|}}.
\]
(see Proposition 1.11).

The punctual objects \(N_{0,i}\) are of the form \(\alpha_{i}^\text{deg} \otimes \delta_{x_i}\) for some unitary scalars \(\alpha_i\) and some points \(x_i\). If \(x_i \neq e\), then
\[
t_{N_{0,i}}(e; k_n) = 0.
\]

Thus, if we denote by \(J \subset I(0)\) the subset where \(x_i = e\) (which has cardinality equal to the multiplicity of the trivial representation in the restriction of \(\rho\) to \(G^\text{geo}\)), then the formula
\[
(4.8) \quad \frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{X}(k_n)} \text{Tr}(\rho(\Theta_{M,k_n}(\chi))) = \sum_{i \in J} \alpha_i^a + O(|k_n|^{-1/2})
\]
74
holds. The subset $J^0 \subset J$ where $\alpha_i = 1$ has cardinality equal to the multiplicity of the trivial representation in the restriction of $\rho$ to $G^\mathrm{ari}_M$. Averaging over $n$ and using

$$\lim_{N \to +\infty} \frac{1}{N} \sum_{1 \leq n \leq N} \alpha_i^2 = 0$$

for $i \in J - J^0$, we conclude that

$$\lim_{N \to +\infty} \frac{1}{N} \sum_{1 \leq n \leq N} |\mathcal{F}(k_n)| \sum_{\chi \in \mathcal{F}(k_n)} \text{Tr}(\rho(\Theta_{M,k_n}(\chi))) = |J^0| + O(|k_n|^{-1/2}),$$

which gives the desired result. \hfill \square

It is useful to state the following corollary of the proof, which is a diophantine version of Schur’s Lemma in our context.

**Corollary 4.6 (Schur’s Lemma).** Let $M$ and $N$ be geometrically simple $\ell$-adic perverse sheaves on $G$ which are pure of weight zero and are objects of $\mathbf{P}^\mathrm{ari}_{\text{int}}(G)$. Let $\mathcal{X}$ be the set of characters which are weakly unramified for $M \oplus N^\vee$. We have

$$\lim_{N \to +\infty} \frac{1}{N} \sum_{n \leq N} |G(k_n)| \sum_{\chi \in \mathcal{F}(k_n)} S(M^\text{int} N^\vee,\chi) = \begin{cases} 1 & \text{if } M \text{ is arithmetically isomorphic to } N, \\ 0 & \text{otherwise.} \end{cases}$$

**Proof.** Proposition 4.3 applied to the perverse sheaf $M \oplus N^\vee$ and the object $Q = \text{Hom}(N,M)$ of the category $(M \oplus N^\vee)^\mathrm{ari}$ (the homomorphisms are in the category $\mathbf{P}^\mathrm{ari}_{\text{int}}(G)$) implies that

$$\frac{1}{|\mathcal{F}(Q)(k_n)|} \sum_{\chi \in \mathcal{F}(Q)(k_n)} S(Q,\chi) = t_Q(e;k_n) + O(|k_n|^{-1/2})$$

for any $n \geq 1$, where

$$S(Q,\chi) = \sum_{x \in G(k_n)} \chi(x)t_Q(x;k_n).$$

Since $\mathcal{F}(Q)$ is generic, and since there is a canonical isomorphism $Q \to M^\text{int} N^\vee$, we deduce that

$$\frac{1}{N} \sum_{n \leq N} \frac{1}{|G(k_n)|} \sum_{\chi \in \mathcal{F}(k_n)} S(M^\text{int} N^\vee,\chi) = \frac{1}{N} \sum_{n \leq N} t_Q(e;k_n) + O(|k_n|^{-1/2})$$

for all $N \geq 1$. Arguing as in the last part of the proof of Theorem 4.4, we see that the right-hand side converges to the multiplicity of the trivial representation in the representation corresponding to $Q$: by the classical form of Schur’s Lemma, this is either 1 or 0, depending on whether $M$ is isomorphic to $N$ or not. \hfill \square

**Remark 4.7.** The proof of Theorem 4.4 allows us to see clearly what is involved in the use of the Cesàro mean in the average equidistribution.

First, we can see that it is necessary in general, unless $G^\mathrm{ari}_M = G^\mathrm{geo}_M$ (see Section 4.6 for statements under this assumption, in particular Proposition 4.18).

Second, we see that the use of the Cesàro average can be generalized to establish the convergence to the limit $\nu_{cp}$ of any sequence of average measures of the form

$$\sum_{n \geq 1} \frac{\varphi_N(n)}{|\mathcal{F}(k_n)|} \sum_{\chi \in \mathcal{F}(k_n)} \delta_{\Theta_{M,k_n}(\chi)},$$
where \( \varphi_N(n) \) are non-negative coefficients that are bounded and satisfy the equality

\[
\lim_{N \to +\infty} \sum_{n \geq 1} \varphi_N(n) \alpha^n = \begin{cases} 
0 & \text{if } \alpha \neq 1, \\
1 & \text{if } \alpha = 1
\end{cases}
\]  

for any complex number \( \alpha \) of modulus 1. The Cesàro case corresponds to \( \varphi_N(n) = 1/N \) for all \( n \leq N \) and \( \varphi_N(n) = 0 \) for \( n > N \), but there are many other possibilities. (In classical terms, as expounded for instance by Hardy \[53\], these \( \varphi_N \) define a “summation method”, and it is elementary that the requirements amounts essentially\(^1\) to asking that this summation method gives the “right” sum \( 1/(1 - \alpha) \) to the geometric series for \( |\alpha| = 1 \) and \( \alpha \neq 1 \).

It is also instructive to view the average probabilistically, interpreting \( \varphi_N \) as the law of a random variable \( X_N \) with values in positive integers. The condition above is the requirement that the equality

\[
\lim_{N \to +\infty} E(e^{i\theta X_N}) = 0
\]

holds for all \( \theta \in \mathbb{R}/2\pi \mathbb{Z} - \{0\} \) (the expectation \( E(e^{i\theta X_N}) \) is known as the characteristic function of \( X_N \)).

Besides the Cesàro case, where \( X_N \) is a random variable uniform on \( \{1, \ldots, N\} \), consider a Poisson distribution \( X_N \) with parameter \( \lambda_N > 0 \), shifted to have support in the positive integers, i.e., let

\[
P(X_N = n) = \varphi_N(n) = e^{-\lambda_N} \frac{\lambda_N^{n-1}}{(n-1)!}
\]

for any positive integers \( N \) and \( n \). The condition above becomes the limit

\[
E(e^{i\theta X_N}) = \exp(i\theta + \lambda_N(e^{i\theta} - 1)) \to 0
\]

as \( N \to +\infty \) for \( \theta \in \mathbb{R}/2\pi \mathbb{Z} - \{0\} \), which holds provided \( \lambda_N \to +\infty \), since the modulus of the left-hand side is \( \exp(\lambda_N(\cos(\theta) - 1)) \).

Intuitively, this means that if we pick a positive integer \( n \) according to a Poisson distribution with large parameter, then pick uniformly a random \( \chi \in \mathcal{X}(k_n) \), then the Frobenius conjugacy class \( \Theta_{M,k_n}(\chi) \) will be distributed like a random \( U\alpha(C)\)-conjugacy class of an element of the maximal compact subgroup \( K \). (A whimsical enough way to do this – according to the Rényi–Turan form of the Erdős–Kac Theorem, see e.g. \[60\], Prop. 4.14 – would be to pick a large integer \( m \geq 1 \) and to take \( n \) to be the number of prime factors of \( m \), which corresponds roughly to having \( \lambda_N = \log \log N \).)

Note however that are also many cases where the condition (4.9) is not true. The most obvious is when \( \varphi_N(N) = 1 \) and \( \varphi_N(n) = 0 \) for \( n \neq N \), corresponding to a limit without extra average at all. In addition, the condition implies that for any integers \( q \geq 1 \) and \( a \in \mathbb{Z} \), we have

\[
P(X_N \equiv a \pmod{q}) = \frac{1}{q} \sum_{b \equiv a \pmod{q}} e^{-2\pi i ab/q} E(e^{2\pi i b X_N/q}) \to \frac{1}{q},
\]

so there is a strong arithmetic restriction that \( X_N \pmod{q} \) converge to the uniform probability measure modulo \( q \) for all \( q \geq 1 \).

Similar remarks apply in an obvious manner to our other equidistribution statements, e.g. to Theorem 2.

---

\(^1\) Precisely, we need that the series \( \sum a_n \) with \( a_1 = \alpha \) and \( a_n = \alpha^n - \alpha^{n-1} \) for \( n \geq 2 \) has “sum” \( \alpha + (\alpha - 1)/(1 - \alpha) = 0 \) for \( |\alpha| = 1 \) and \( \alpha \neq 1 \).
4.4. Equidistribution for arithmetic Fourier transforms

We now deduce from Theorem 4.4 the equidistribution of the exponential sums defined by

\[ S(M, \chi) = \sum_{x \in G(k_n)} \chi(x) r_M(x; k_n). \]

In fact, note that these sums make sense for all characters \( \chi \in \hat{G}(k_n) \), and we can indeed prove equidistribution for all of them. This implies Theorem 2 from the introduction. As a final addition, we prove an equidistribution statement for the arithmetic Fourier transforms of all objects \( M \) of \( D^b_c(G) \) which are mixed semiperverse sheaves of weights \( \leq 0 \). This is of interest especially in more analytic applications, since the condition of being semiperverse and that of being mixed of weights \( \leq 0 \) are much more flexible, and easier to check, than those of being perverse and pure.

**Theorem 4.8.** Let \( k \) be a finite field and let \( G \) be a connected commutative algebraic group over \( k \). Let \( \ell \) be a prime number distinct from the characteristic of \( k \).

Let \( M \) be an object of \( D^b_c(G) \). Assume that \( M \) is semiperverse of weights \( \leq 0 \). Let \( N \) be the perverse subsheaf of weight 0 of the arithmetic semisimplification of the perverse cohomology sheaf \( p\mathcal{H}^0(M) \).

Let \( r \geq 0 \) be the tannakian dimension of \( N \). Let \( K \subseteq G_{\text{ari}}(\mathbb{C}) \subset GL_r(\mathbb{C}) \) be a maximal compact subgroup of the arithmetic tannakian group of \( N \). Denote by \( \mu \) the Haar probability measure on \( K \) and by \( \nu \) its image by the trace.

The families of exponential sums \( S(M, \chi) \) for \( \chi \in \hat{G}(k_n) \) become \( \nu \)-equidistributed on average as \( n \to +\infty \).

**Proof.** We first assume that \( M \) is perverse and pure of weight 0, so that the object \( N \) coincides with \( M \). We then observe that, by the generic vanishing theorem, it suffices to prove that the families of exponential sums associated to \( \chi \in \Xi_w(M) \) become \( \nu \)-equidistributed on average, since for any bounded continuous function \( f : \mathbb{C} \to \mathbb{C} \), we have

\[ \left| \frac{1}{|G(k_n)|} \sum_{\chi \in \hat{G} - \Xi_w(M)(k_n)} f(\text{Tr} \Theta_{M,k_n}(\chi)) \right| \leq \|f\|_\infty \frac{||\hat{G} - \Xi_w(M)(k_n)||}{|G(k_n)|} \to 0 \]

because \( \Xi_w(M) \) is generic. But since \( \text{Tr} \nu_{c_p} = \nu \), this equidistribution follows from Theorem 4.4 by considering the composition \( K \to U_r(\mathbb{C}) \overset{\text{Tr}}{\to} \mathbb{C} \).

We now consider the general case. We denote by \( M_0 \) the arithmetic semisimplification of the perverse sheaf \( p\mathcal{H}^0(M) \), and by \( N' \) the perverse sheaf such that \( M_0 = N \oplus N' \), defined using the weight filtration on \( M_0 \); the perverse sheaf \( N_0 \) is mixed of weights \( \leq -1 \).

Since \( M \) is semiperverse of weights \( \leq 0 \), we have \( p\mathcal{H}^i(M) = 0 \) for \( i \geq 1 \), and \( p\mathcal{H}^{-i}(M) \) is of weights \( \leq -i \leq -1 \) for all \( i \geq 1 \) (see [6, Th. 5.4.1]).

For any \( n \geq 1 \) and \( \chi \in \hat{G}(k_n) \), we have the equality

\[ S(M, \chi) = S(N, \chi) + S(N', \chi) + \sum_{i \geq 1} (-1)^i S(p\mathcal{H}^{-i}(M), \chi). \]

By generic vanishing and the trace formula (see Theorem 6.1 below, applied to \( N'(-1/2) \) and \( p\mathcal{H}^{-i}(M)(-1/2) \) for \( i \geq 1 \), which are mixed perverse sheaves of weights \( \leq 0 \)), there exists a generic subset \( \Xi \subseteq \hat{G} \) such that we have

\[ S(N', \chi) + \sum_{i \geq 1} (-1)^i S(p\mathcal{H}^{-i}(M), \chi) \ll \frac{1}{|k_n|^{1/2}}. \]
for all $n \geq 1$ and $\chi \in \mathcal{X}(k_n)$. This implies that the sequence $(\varpi_n)$ of probability measures defined as averages of delta masses at the points

$$S(N', \chi) + \sum_{i \geq 1} (-1)^i S(p^{i\mathcal{H}-i}(M), \chi)$$

for all $\chi \in \hat{G}(k_n)$ converges to zero in probability, i.e., that for any fixed real number $\varepsilon > 0$, the limit

$$\lim_{n \to +\infty} \varpi_n(\{t > \varepsilon\}) = 0$$

holds.

By the first case applied to the perverse sheaf $N$, the sums $S(N, \chi)$ become $\nu$-equidistributed on average as $n \to +\infty$, and the formula (4.10) ensures then that the same holds for the $S(M, \chi)$ (see, e.g., [79, Cor. B.4.2] for the simple probabilistic argument that leads to this conclusion). □

**Remark 4.9.**

(1) As we will see later, it is often of interest to attempt to apply equidistribution of exponential sums to the test function $z \mapsto z^m$ or $z \mapsto |z|^m$ for some integer $m \geq 1$. Such functions are continuous but not bounded on $\mathbb{C}$, so that Theorem 4.8 does not apply, and Theorem 4.4 only gives the equidistribution for weakly unramified characters. In these attempts, the contribution of the other characters may therefore need to be handled separately (see for instance the proof of Theorem 10.9).

(2) See Chapter 8 for an application of this theorem to a question of independence of $\ell$ of tannakian groups.

**Example 4.10.** Let $k = \mathbb{F}_p$, and let $\psi$ be the additive character on $k$ such that $\psi(x) = e(x/p)$ for $x \in k$. Let $X \subset G$ be a locally-closed subvariety of $G$ of dimension $d \geq 1$, and let $f : X \to \mathbb{A}^1$ be a non-zero function on $X$. Then there is a semiperverse sheaf $M$ on $G$, mixed of weights 0, such that the trace function of $M$ is given by the formula

$$\ell_M(x; \mathbb{F}_p) = \begin{cases} (-1)^d p^{-nd/2} e(T \mathbf{F}_p^n/(f(x))/p) & \text{if } x \in X(\mathbb{F}_p) \\ 0 & \text{otherwise.} \end{cases}$$

for $n \geq 1$ and $x \in G(k_n)$, namely

$$M = j_! f^* \mathcal{L}_\psi[d](d/2),$$

where $j : X \to G$ is the natural immersion.

Hence Theorem 4.8 implies that the exponential sums

$$\frac{1}{p^{nd/2}} \sum_{x \in X(\mathbb{F}_p)} \chi(x) e\left(\frac{f(x)}{p}\right)$$

for $\chi \in \hat{G}(\mathbb{F}_p)$ always satisfy some equidistribution theorem on average.

A similar property holds if we fix a non-trivial multiplicative character $\eta$ of $\mathbb{F}_p^\times$ and an invertible function $g : X \to \mathbb{G}_m$, and consider the exponential sums

$$\frac{1}{p^{nd/2}} \sum_{x \in X(\mathbb{F}_p)} \chi(x) \eta(g(x))$$

(using the object $j_! g^* \mathcal{L}_\eta[d](d/2)$, which is also mixed and semiperverse of weights $\leq 0$).
4.5. Equidistribution for conjugacy classes

We keep the notation of the previous sections. If the object $M$ that we consider is generically unramified, then we can prove equidistribution at the level of the Frobenius conjugacy classes in the maximal compact subgroup of the arithmetic tannakian group.

**Theorem 4.11 (Equidistribution on average).** Let $k$ be a finite field and let $G$ be a connected commutative algebraic group over $k$. Let $\ell$ be a prime number distinct from the characteristic of $k$.

Let $M$ be an $\ell$-adic perverse sheaf on $G$ that is arithmetically semisimple, pure of weight zero and generically unramified. Let $X = X(M)$ be the set of unramified characters for $M$. Let $K$ be a maximal compact subgroup of the arithmetic tannakian group $G_{\text{ari}}(M)$ of $M$, and denote by $\mu^\#$ the direct image of the Haar probability measure $\mu$ on $K$ by the projection to the set $K^\sharp$ of conjugacy classes of $K$.

Then the families of unitary Frobenius conjugacy classes $(\Theta_{M,k_n}(\chi))_{\chi \in X(k_n)}$ become $\mu$-equidistributed on average in $K^\sharp$ as $n \to +\infty$.

**Proof.** By Theorem 3.28 and the definition of generic sets, we know that $|X(k_n)| \sim |G(k_n)|$ as $n \to +\infty$, and hence the sets of unramified conjugacy classes are non-empty for $n$ large enough.

By the Peter-Weyl theorem, any continuous central function $f: K \to \mathbb{C}$ is a uniform limit of linear combinations of characters of finite-dimensional unitary irreducible representations of $K$, and hence it suffices to prove the formula (4.1) when $f$ is such a character. For the trivial representation, both sides are equal to 1. If the representation is non-trivial, then the integral on the right-hand side vanishes, and we are reduced to showing that the limit on the left-hand side exists and is equal to 0. We thus consider a non-trivial irreducible representation $\varrho$ of $K$, which we identify with a non-trivial irreducible algebraic $\mathbb{Q}_\ell$-representation of the arithmetic tannakian group $G_{\text{ari}}^M$ by Weyl’s unitarian trick (see, e.g., [61, 3.2] for this step); applying the next proposition then completes the proof. \qed

**Proposition 4.12.** With notation as in Theorem 4.11, let $\varrho$ be a non-trivial irreducible unitary representation of $K$, identified with a non-trivial irreducible representation of $G_{\text{ari}}^M$.

(1) If the restriction of $\varrho$ to $G_{\text{geo}}^M$ is non-trivial, then

\[
\frac{1}{|X(k_n)|} \sum_{\chi \in X(k_n)} \text{Tr}(\varrho(\Theta_{M,k_n}(\chi))) \ll \frac{1}{\sqrt{|k_n|}}
\]

for all $n$ such that $X(k_n)$ is not empty.

(2) If the restriction of $\varrho$ to $G_{\text{geo}}^M$ is trivial, then

\[
\lim_{N \to +\infty} \frac{1}{N} \sum_{1 \leq n \leq N, X(k_n) \neq \emptyset} \frac{1}{|X(k_n)|} \sum_{\chi \in X(k_n)} \text{Tr}(\varrho(\Theta_{M,k_n}(\chi))) = 0.
\]

**Proof.** (1) We assume that the restriction of $\varrho$ to the geometric tannakian group is non-trivial.

Let $\varrho(M)$ denote the object of the tannakian category $\langle M \rangle_{\text{ari}}$ corresponding to the representation $\varrho$ of the arithmetic tannakian group $G_{\text{ari}}^M$; this is a simple perverse sheaf on $G$. 

79
We have $\mathcal{X} \subset \mathcal{X}_F(\varrho(M))$. Applying Proposition 4.3 to the object $N = \varrho(M)$, we obtain

$$\frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{X}(k_n)} \text{Tr}(\varrho(\Theta_{M,k_n}(\chi))) = t_{\varrho(M)}(e;k_n) + O(|k_n|^{-1/2})$$

since the conjugacy class $\Theta_{M,k_n}(\chi)$ coincides with $\Theta_{M,k_n}(\chi)$ when $\chi$ is unramified for $M$.

Since $\varrho(M)$ is a simple perverse sheaf on $G$, the classification of [6, Th. 4.3.1 (ii)] shows that there exist an irreducible closed subvariety $s : Y \to G$ of dimension $r$, an open dense smooth subvariety $j : U \to Y$, and an irreducible lisse $\mathcal{F}$-sheaf $\mathcal{F}$ on $U$ such that $\varrho(M) = s_*j_!r_!\mathcal{F}[r]$. Since the functors $s_*$ and $j_!$ are weight-preserving, the sheaf $\mathcal{F}$ is pure of weight $-r$.

If $r = 0$, then $Y$ consists of a closed point of $G$, which must be different from the neutral element $e$, since otherwise $\varrho(M)$ would be geometrically trivial, contrary to the assumption in (1). In that case, we have therefore $t_{\varrho(M)}(e;k_n) = 0$. On the other hand, if $r \geq 1$ we get

$$(4.14) \quad t_{\varrho(M)}(e;k_n) \ll \frac{1}{\sqrt{|k_n|}}$$

(by Proposition 1.11), which concludes the proof of (1).

(2) We assume that the restriction of the representation $\varrho$ to $G_{M,\text{geo}}^\text{ari}$ is trivial. Then $\varrho$ has dimension 1 since the quotient $G_{M,\text{ari}}^\text{geo}/G_{M,\text{geo}}^\text{ari}$ is abelian (Proposition 3.39).

Let $Q$ be the set of integers $n \geq 1$ such that $\mathcal{X}(k_n)$ is not empty; it contains all sufficiently large integers. It follows from Proposition 3.39 that there exists an element $\xi$ of $G_{M,\text{geo}}^\text{ari}/G_{M,\text{geo}}^\text{ari}$, generating a Zariski-dense subgroup of this group, such that $\varrho(\Theta_{M,k_n}(\chi)) = \varrho(\xi)^n$ for any $\chi \neq 1$ and any $\chi \in G(k_n)$ unramified for $M$. Moreover, we have $\varrho(\xi) \neq 1$, since otherwise the representation $\varrho$ would be trivial. We conclude that

$$\frac{1}{N} \sum_{1 \leq n \leq N} \frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{X}(k_n) \backslash \mathcal{X}(k_n) \neq \emptyset} \text{Tr}(\varrho(\Theta_{M,k_n}(\chi))) = \frac{1}{N} \sum_{1 \leq n \leq N} \varrho(\xi)^n$$

converges to 0 as $N \to +\infty$ by summing a non-trivial geometric progression.

\[\square\]

Remark 4.13. For certain reductive groups $G \subset GL_r(C)$, a conjugacy class in a maximal compact subgroup $K$ of $G$ is determined by its characteristic polynomial (equivalently, the exterior powers of the standard representation generate the representation ring of $G$). If $G_{M,\text{ari}}^\text{geo}(C)$ has this property, then Theorem 4.4 implies a version of Theorem 4.11, even if $M$ is not generically unramified.

If $G$ is semisimple, this property holds, for instance, for $SL_r(C) \subset GL_r(C)$, for $Sp_{2r}(C) \subset GL_{2r}(C)$, and for $G_2(C) \subset GL_7(C)$. Indeed, the first two cases are explained by Katz in [61, Lemma 13.1, Remark 13.2]; in the third case, we note that the second fundamental representation of $G_2(C)$ is virtually $\wedge^2 \text{Std} – \text{Std}$ (see, e.g., [45, p. 353]) so that the exterior powers of the standard 7-dimensional representation generate the representation ring.

We deduce immediately from Theorem 4.11 a useful corollary, analogue to some classical consequences of the Chebotarev density theorem.

Corollary 4.14. Let $k$ be a finite field and let $G$ be a connected commutative algebraic group over $k$. Let $M$ be a perverse sheaf on $G$ which is arithmetically semisimple, pure of weight zero and generically unramified.

Let $S$ be any finite subset of $\hat{G}$. The union of the unitary Frobenius conjugacy classes of $M$ associated to unramified characters in $\hat{G} – S$ is dense in a maximal compact subgroup of $G_{M,\text{ari}}^\text{geo}(C)$. 80
4.6. Equidistribution without average

We continue again with the previous notation. If we make the extra assumption that the geometric and the arithmetic tannakian groups coincide, then the equidistribution of Frobenius conjugacy classes holds without averaging over \( n \). We summarize the variants of the previous theorems in this situation.

Theorem 4.15 (Equidistribution without average). Let \( M \) be an \( \ell \)-adic perverse sheaf on \( G \) that is arithmetically semisimple, pure of weight zero. We assume that the inclusion \( G^\text{geo}_M \subset G^\text{ari}_M \) is an equality.

Let \( r \geq 0 \) be the tannakian dimension of \( M \). Let \( K \subset G^\text{ari}_M(\mathbb{C}) \subset \text{GL}_r(\mathbb{C}) \) be a maximal compact subgroup of the arithmetic tannakian group of \( M \). Denote by \( \mu \) the Haar probability measure on \( K \), by \( \nu_{cp} \) the direct image by the map \( K \to \text{U}_r(\mathbb{C}) \), by \( \nu \) the image by the trace, and by \( \mu^\sharp \) the image by the map \( K \to K^\sharp \).

(1) The families of unitary Frobenius conjugacy classes \( (\Theta_{M,k_n}(\chi))_{\chi \in \mathcal{X}_w(M)(k_n)} \) become \( \nu_{cp} \)-equidistributed as \( n \to +\infty \).

(2) The families of exponential sums \( S(M,\chi) \) for \( \chi \in \hat{G}(k_n) \) become \( \nu \)-equidistributed as \( n \to +\infty \).

(3) If \( M \) is generically unramified, then the family of conjugacy classes \( (\Theta_{M,k_n}(\chi))_{\chi \in \mathcal{X}(M)(k_n)} \) become \( \mu^\sharp \)-equidistributed as \( n \) goes to infinity.

Proof. This follows from the Weyl Criterion as in the proof of Theorems 4.4, 4.8 and 4.11; in the case of the last statement, for instance, we use only the first part of Proposition 4.12 (as we may since a non-trivial irreducible representation of \( G^\text{ari}_M \) is a non-trivial irreducible representation of \( G^\text{geo}_M \) under the assumption).

Remark 4.16. There is an obvious further variant of Theorems 4.15 and of the case of mixed semiperverse objects of weights \( \leq 0 \) of 4.8: if \( M \) is mixed semiperverse of weights \( \leq 0 \), with \( N \) as in Theorem 4.8 such that \( G^\text{ari}_N = G^\text{geo}_N \), then the discrete Fourier transform becomes equidistributed towards the measure \( \nu \) without average over \( n \).

There is a converse to Theorem 4.15. In fact, there is a statement which is valid for an individual representation of the unitary group (this will be useful in Chapter 9).

Proposition 4.17. Let \( M \) be an \( \ell \)-adic perverse sheaf on \( G \) that is arithmetically semisimple and pure of weight zero. Let \( r \) be the tannakian dimension of \( M \) and let \( \mathcal{X} = \mathcal{X}_w(M) \) be the set of weakly unramified characters for \( M \). Let \( \rho \) be a finite-dimensional unitary representation of \( \text{U}_r(\mathbb{C}) \). Assume that the sequence

\[
\frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{X}(k_n)} \text{Tr}(\rho(\Theta_{M,k_n}(\chi))),
\]

defined for all integers \( n \geq 1 \) such that \( \mathcal{X}(k_n) \) is not empty, has a limit. Then this limit is equal to the multiplicity of the trivial representation in the restriction of \( \rho \) to \( G^\text{geo}_M \).

Proof. We use the notation in the proof of Theorem 4.4. Taking the equality (4.8) into account, the assumption of the statement means that the limit

\[
\lim_{n \to +\infty} \sum_{i \in J} \alpha_i^n
\]

exists, where the complex numbers \( \alpha_i \) have modulus 1 and the set \( J \) has cardinality equal to the multiplicity of the trivial representation in the restriction of \( \rho \) to \( G^\text{geo}_M \). We claim that the existence of this limit implies the equality \( \alpha_i = 1 \) for all \( i \in J \), so that the limit is equal to \( |J| \), as desired.
Indeed, let \( L \subset J \) be the set of \( \alpha_i \neq 1 \). The sequence
\[
\sum_{i \in L} \alpha_i^n
\]
converges as well, and its limit must be zero since it converges to 0 on average over \( n \leq N \). However, the lower bound
\[
\limsup_{n \to +\infty} \left| \sum_{i \in L} \alpha_i^n \right| \geq |L|^{1/2}
\]
holds (see, e.g., [59, Lemma 11.41]), so we deduce that \( L \) is empty, which proves the claim. \( \square \)

A more global form of this converse, for generically unramified objects, is the following:

**Proposition 4.18.** Let \( M \) be an \( \ell \)-adic perverse sheaf on \( G \) that is arithmetically semisimple and pure of weight zero. Assume that \( M \) is generically unramified. Let \( r \) be the tannakian dimension of \( M \) and let \( X = X_w(M) \) be the set of unramified characters for \( M \). If the sequence of probability measures
\[
\frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{X}(k_n)} \delta_{\Theta_{M,k_n}(\chi)},
\]
defined when \( \mathcal{X}(k_n) \) is not empty, converges weakly to some probability measure, then we have the equality \( G_{\text{ari}} M = G_{\text{geo}} M \).

**Proof.** Suppose that \( G_{\text{geo}} M \neq G_{\text{ari}} M \). By Proposition 3.39, there exists an element \( \xi \neq 1 \) of \( G_{\text{ari}} M / G_{\text{geo}} M \) which generates a Zariski-dense subgroup of this group, which is abelian. Thus there exists an irreducible representation \( \rho \) of the quotient \( G_{\text{ari}} M / G_{\text{geo}} M \) such that \( \rho(\xi) \neq 1 \); for any \( n \geq 1 \) and any \( \chi \in \hat{G}(k_n) \) unramified for \( M \), the equality \( \rho(\Theta_{M,k_n}(\chi)) = \rho(\xi)^n \) holds.

Let \( \mathcal{X} \) be the set of characters unramified for \( M \). Then
\[
\frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{X}(k_n)} \text{Tr}(\rho(\Theta_{M,k_n}(\chi))) = \rho(\xi)^n
\]
for all \( n \geq 1 \) for which \( \mathcal{X}(k_n) \) is not empty. Since \( \rho(\xi) \neq 1 \), this quantity does not converge as \( n \to +\infty \), which implies the proposition by contraposition. \( \square \)

### 4.7. Horizontal equidistribution

The proof of Theorem 4.11 relies crucially on the estimates in the stratified vanishing theorem 2.3. We expect (see Remark 2.4) that the implied constants in these estimates depend only on the complexity of the perverse sheaf \( M \) (as is the case for unipotent groups).

Under the assumption that such a statement is valid, and in fact that this holds for the size of the set of unramified characters, one can obtain equidistribution statements for finite fields under the condition that their size tends to infinity (for instance, for \( F_p \) as \( p \to +\infty \); compare with [68, Ch. 28–29]).

We include a conditional statement of this type, since we expect that there should be progress soon concerning the underlying uniformity question. We leave to the interested reader the task of formulating variants similar to Theorems 4.8 and 4.4.

**Theorem 4.19 (Horizontal equidistribution).** Let \( \ell \) be a prime number. Let \( N \geq 1 \) be an integer and let \( (G, u) \) be a quasi-projective commutative group scheme over \( \mathbb{Z}[1/\ell N] \) such that, for all primes \( p \nmid \ell N \), the fiber \( G_p \) of \( G \) over \( F_p \) is a connected commutative algebraic group for which the estimate
\[
|\hat{G}_p(F_p^n) - X(M)(F_p^n)| \ll c_u(M)p^n(\dim(G_p)-1)
\]
holds.
holds for all primes \( p \) and \( n \geq 1 \) and all arithmetically semisimple objects \( M \) in \( \text{Perv}_{\text{int}}(G_p) \) which are generically unramified.

Let \( (M_p)_{p \nmid N\ell} \) be a sequence of arithmetically semisimple objects in \( \text{Perv}_{\text{int}}(G_p) \) which are pure of weight zero. Suppose that the tannakian dimension \( r \) of \( M_p \) is independent of \( p \), and that for all \( p \), we have \( G^\text{ari}_{M_p} = G^\text{geo}_{M_p} \), and that this common reductive group is conjugate to a fixed subgroup \( G \) of \( \text{GL}_r(\overline{\mathbb{Q}}_\ell) \).

Let \( K \) be a maximal compact subgroup of \( G(\mathbb{C}) \) and let \( \mu^\# \) be the direct image of the Haar probability measure on \( K \) to \( K^\# \).

Let \( \mathcal{X}_p \) be the set of characters \( \chi \in \hat{G}_p(\mathbb{F}_p) \) which are unramified for the object \( M_p \).

If we have \( c_u(M_p) \ll 1 \) for all \( p \nmid N\ell \), then the families of conjugacy classes \( (\Theta_{M_p,\mathbb{F}_p(\chi)})_{\chi \in \mathcal{X}_p} \) become \( \mu^\# \)-equidistributed in \( K^\# \) as \( p \to +\infty \).

**Proof.** The argument follows that of Theorem 4.11; it suffices to prove the estimate

\[
\frac{1}{|\mathcal{X}_p|} \sum_{\chi \in \mathcal{X}_p} \text{Tr} \left( \varrho(\Theta_{M_p,\mathbb{F}_p(\chi)}) \right) \ll \frac{1}{\sqrt{p}}
\]

for all \( p \nmid N\ell \). The proof of this is similar to the first part of Proposition 4.12, noting that, under our assumptions, the implied constants in the key bounds (4.14), (4.5), (4.6) and (4.7) are independent of \( p \), since the complexity of \( M_p \) is bounded independently of \( p \), and hence also that of \( \varrho(M_p) \) by [100, Prop. 6.33].

**Remark 4.20.** (1) For \( G \) unipotent, results of this form are unconditional by Proposition 2.7 (the case of \( G_a \) essentially goes back to Katz [61], whereas the case of an arbitrary power of \( G_a \) follows from [100, Th. 7.22]). For \( G = G_m \), a similar statement is proved by Katz in [68, Th. 28.1].

(2) The result is also unconditional in the case of abelian varieties (see Remark 2.4). We expect that a careful look at the proof of the generic vanishing theorem will also show that it is unconditional for \( G_m \times G_a \). The case of tori of dimension \( \geq 2 \) is however not yet known.
Part 2

Applications
Description of applications

The remainder of the book is devoted to applications of the theoretical results of the first part of this book. We split these applications in further chapters as follows:

1. We define in Chapter 5 the analogue of L-functions for the Fourier–Mellin transforms. We establish with its help that the arithmetic tannakian group is infinite for many non-punctual objects on abelian varieties.

2. We present in Chapter 6 the concrete analytic translation of the stratified vanishing theorem to stratification of estimates for exponential sums, in the spirit of Katz–Laumon [71] and Fouvry–Katz [35].

3. We discuss in Chapter 7 a “generic Fourier inversion formula”, which shows that two semisimple perverse sheaves are isomorphic in the category $\overline{\mathcal{D}}^{\text{vir}}(G)$ if and only if the associated exponential sums coincide for a generic set of characters.

4. In Chapter 8, we add a theoretical application of equidistribution in direction of independence of $\ell$ properties of the tannakian groups associated to a compatible system of $\ell$-adic complexes.

5. In applications of equidistribution to concrete perverse sheaves, the main issue is to determine the tannakian group. The main tool that we will use for this purpose is Larsen’s Alternative, and its link with equidistribution. We present this result (and a new variant for the exceptional group $E_6$) in Chapter 9.

6. Then in the following chapters, we present examples of equidistribution and concrete applications; these involve the following groups:

- the product $G_m \times G_a$, which (apart from unipotent groups) is probably the simplest group of dimension $\geq 2$ (Chapter 10); this corresponds to rather natural families of exponential sums parameterized by both an additive character and a multiplicative character.

- higher-dimensional tori, with applications to the study of the variance of arithmetic functions on $k[t]$ in arithmetic progressions modulo square-free polynomials (see Chapter 11).

- the jacobian of a curve (Chapter 12); the application we present is a generalization of an unpublished result of Katz (which answered a question of Tsimerman).

- in the same chapter, we also consider an example where the group under consideration is the intermediate jacobian of a smooth projective cubic hypersurface of dimension 3, which is an abelian variety of dimension 5 (see Chapter 12.2).
Über eine neue Art von L-Reihen

5.1. \( \hat{L} \)-functions

Let \( k \) be a finite field, with algebraic closure \( \overline{k} \) and intermediate extensions \( k_n \). We fix as usual a prime \( \ell \) different from the characteristic of \( k \). Let \( G \) be a connected commutative algebraic group over \( k \), and let \( d \) be its dimension. We denote by \( e \) the neutral element of \( G \).

By analogy with algebraic varieties over \( k \), we can define “L-functions” for objects of \( D^b_c(G) \), where suitable characters \( \chi \in \hat{G} \) play the role of primes in an “Euler product”.

We denote by \( \hat{G}^* \subset \hat{G} \) the set of characters such that \( \chi \in \hat{G}^*(k_n) \) if and only if there is no \( d \mid n \) with \( d < n \) such that \( \chi = \chi' \circ N_{k_n/k_d} \). We say that elements of \( \hat{G}^* \) are primitive, and for \( \chi \in \hat{G}^*(k_n) \), we put \( \deg(\chi) = n \). We then denote by \( \hat{G}^\ast \) the quotient set of \( \hat{G}^* \) by the equivalence relation defined by \( \chi_1 \sim \chi_2 \) if and only if \( \deg(\chi_1) = \deg(\chi_2) \) and \( \chi_2 = \chi_1 \circ \text{Fr}_{k^d \deg(\chi_1)} \) for some integer \( j \in \mathbb{Z} \). There are \( \deg(\chi) \) primitive characters equivalent to a given \( \chi \in \hat{G}^* \).

Definition 5.1 (\( \hat{L} \)-function). Let \( M \) be an object of \( D^b_c(G) \). The Fourier-\( \hat{L} \)-function, or \( \hat{L} \)-function, of \( M \) is the formal power series

\[
\hat{L}(M, T) = \prod_{\chi \in [\hat{G}]} \det(1 - T^{\deg(\chi)} \text{Fr}_{k^d \deg(\chi)} | H^*_c(G_{\overline{k}}, M_\chi))^{-1} \in \overline{\mathbb{Q}}_\ell[[T]].
\]

This is similar to the definition

\[
L(M, T) = \prod_{x \in [X]} \det(1 - T^{\deg(x)} \text{Fr}_{k^d \deg(x)} | M_x)^{-1} \in \overline{\mathbb{Q}}_\ell[[T]]
\]

of the L-function of \( M \) on an arbitrary algebraic variety \( X \) over \( k \), with primitive characters replacing the set \([X]\) of closed points of \( X \).

Indeed, if \( G \) is unipotent of dimension \( d \), and \( FT(M) \) denotes the Fourier transform of \( M \) on the (or “a”) Serre dual \( G^\vee \) defined with respect to some additive character \( \psi \), as in Section 2.2, then we obtain the identity

\[
\hat{L}(M, T) = L(FT(M), |k|^dT),
\]

(e.g. by the formula (5.2) below, since the stalk of \( FT(M) \) at the origin is canonically isomorphic to \( M \) by the proper base change theorem, and \( |G(k_n)| = |k|^nd \) in this case).

In general, however, we obtain “new” L-functions. Their fundamental properties, including rationality, are given by the next proposition.

Proposition 5.2. Let \( M \) be an object of \( D^b_c(G) \). We denote as usual

\[
S(M, \chi) = \sum_{x \in G(k_n)} \chi(x)t_M(x; k_n)
\]

89
for \( n \geq 1 \) and \( \chi \in \hat{G}(k_n) \).

(1) The \( \hat{L} \)-function satisfies

\[
\hat{L}(M, T) = \exp \left( \sum_{n \geq 1} \left( \sum_{\chi \in \hat{G}(k_n)} S(M, \chi) \frac{T^n}{n} \right) \right)
\]

(5.1)

(5.2)

(2) The \( \hat{L} \)-function is a rational function; if \( M \) is a mixed complex, then the zeros and poles of \( \hat{L}(M, T) \) are \(|k|\)-Weil numbers of some weights.

(3) For any \( \chi \in \hat{G}(k) \), the equality \( \hat{L}(M_\chi, T) = \hat{L}(M, T) \) holds.

Proof. The proof of the formula (5.1), like in the classical case, is a simple consequence of the trace formula. Precisely, we apply the operator \( f(T) \mapsto T \frac{d}{d \log f(T)} \) to both sides of this equality.

On the left-hand side, after expressing the determinant as alternating product of the determinants on the various groups \( H^*_c(G_\bar{k}, M_\chi) \), we obtain

\[
T \frac{d}{d \log \hat{L}(M, T)} = \sum_{\chi \in \hat{G}} \deg(\chi) \sum_{m \geq 1} T^m \deg(\chi) \Tr(Fr_{k_{deg(\chi)}}^m | H^*_c(G_\bar{k}, M_\chi)) = \sum_{n \geq 1} T^n \sum_{d|n} \sum_{\chi \in \hat{G}(k_d)} d \Tr(Fr_{k_d}^{n/d} | H^*_c(G_\bar{k}, M_\chi)).
\]

On the right-hand side of (5.1), we obtain

\[
\sum_{n \geq 1} T^n \sum_{\chi \in \hat{G}(k_n)} S(M, \chi),
\]

and hence the formula is equivalent with the fact that the identity

\[
(5.3) \sum_{d|n} \sum_{\chi \in \hat{G}(k_d)} d \Tr(Fr_{k_d}^{n/d} | H^*_c(G_\bar{k}, M_\chi)) = \sum_{\chi \in \hat{G}(k_n)} S(M, \chi)
\]

holds for any integer \( n \geq 1 \).

Let \( n \geq 1 \). To establish (5.3) for \( n \), we begin with the trace formula (A.4), which implies that

\[
S(M, \chi) = \Tr(Fr_{k_n} | H^*_c(G_\bar{k}, M_\chi)),
\]

for any \( \chi \in \hat{G}(k_n) \).

There exists a unique divisor \( d \) of \( n \) and a character \( \chi_0 \in \hat{G}^*(k_d) \) such that \( \chi = \chi_0 \circ N_{k_n/k_d} \). The map sending \( \chi \) to the equivalence class of \( \chi_0 \) in \( \hat{G} \) has image the subset of classes \([\eta]\) of primitive characters \( \eta \) with degree dividing \( n \), and for any such class \([\eta]\), there are exactly \( \deg([\eta]) \) characters \( \chi \in \hat{G}(k_n) \) mapping to \([\eta]\). Moreover, there are canonical isomorphisms

\[
H^*_c(G_\bar{k}, M_\chi) \simeq H^*_c(G_\bar{k}, M_\eta),
\]

with the actions of \( Fr_{k_n} \) corresponding to that of \( Fr_{k_d}^{n/d} \), so that

\[
S(M, \chi) = \Tr(Fr_{k_d}^{n/d} | H^*_c(G_\bar{k}, M_\eta))
\]

for all \( \chi \) mapping to \([\eta]\). This implies the desired identity (5.3).
The second formula (5.2) for \( \hat{L}(M, T) \) follows immediately from (5.1), since orthogonality of characters implies that the formula
\[
\sum_{\chi \in \hat{G}(k_n)} S(M, \chi) = |G(k_n)| t_M(e; k_n)
\]
holds for all \( n \geq 1 \).

Using next the trace formula and the Riemann Hypothesis to compute \( |G(k_n)| \) as an alternating sum of \(|k|\)-Weil numbers, it follows that
\[
|G(k_n)| t_M(e; k_n) = \sum_{i \in I} \varepsilon_i \alpha_i^n
\]
for some finite set \( I \), some \( \varepsilon_i \in \{-1, 1\} \), and some \(|k|\)-Weil numbers \( \alpha_i \). The second assertion follows then from the usual power series expansion
\[
\exp \left( \sum_{n \geq 1} \frac{\alpha^n T^n}{n} \right) = \frac{1}{1 - \alpha T}.
\]

The final assertion is clear either from the definition, or from the above, noting that \( t_M(\chi; e; k_n) = t_M(e; k_n) \) for any \( \chi \in \hat{G}(k) \) and \( n \geq 1 \). \( \square \)

**Remark 5.3.** To illustrate the differences with L-functions, we note that if \( G \) is not unipotent, then the \( \hat{L} \)-function is very rarely a polynomial or the inverse of a polynomial, and does not satisfy in general any functional equation of the form
\[
\hat{L}(M, T) = (\text{simple quantities}) \times \hat{L}(M^\prime, q^\alpha T^{-1})
\]
as is the case for the standard L-function of \( M \) (this is related to the remark of Boyarchenko and Drinfeld [14, §1.6, Example 1.8]).

To give a concrete example, take \( G = G_m \). In this case, we deduce from (5.2) the formula
\[
\hat{L}(M, T) = \exp \left( \sum_{n \geq 1} \frac{\alpha^n T^n}{n} \right) = \frac{L(M_e, |k| T)}{L(M_e, T)}
\]
where \( M_e \) is the stalk of \( M \) at \( e \) (where \( L(M_e, T) \) is the L-function of the stalk of \( M \) at \( e \), viewed as a complex on \( \{e\} \)). If the L-function \( L(M_e, T) \) is not constant, then there can never be cancellation in this quotient to obtain a polynomial or the inverse of a polynomial. If (say) we have
\[
L(M_e, T) = (1 - \alpha T)(1 - \alpha^{-1} T),
\]
then
\[
\hat{L}(M, T) = \frac{(1 - |k| \alpha T)(1 - |k| \alpha^{-1} T)}{(1 - \alpha T)(1 - \alpha^{-1} T)},
\]
and this satisfies no simple functional relation.

We conclude with a result that will be useful in the next section when performing induction.

**Proposition 5.4.** Let \( G \) be a semialgebraic variety over \( k \). Let \( S \) be a tac of \( G_k \) defined by a morphism \( \pi: G \to G' \) over \( k \) and a character \( \chi_0 \in \hat{G}(k) \), and let \([S]\) denote the classes in \( \hat{G} \) of elements of \( S \). Let \( M \) be an object of \( D^b_c(G) \). We then have
\[
\prod_{\chi \in [S]} \det(1 - T^{\deg(\chi)} \text{Fr}_{k_{\deg(\chi)}} | H^*_c(G_k, M_{\chi}))^{-1} = \hat{L}(R\pi_!M_{\chi_0}, T).
\]
Proof. We have $\chi \in [S]$ if and only if $\chi = \chi_0 \cdot (\pi^*\eta)$ for some $\eta \in \hat{G}^r$, with $\deg(\chi) = \deg(\eta)$. By the projection formula, we have a canonical isomorphism

$$H^*_c(G_k, M_\chi) = H^*_c(G_k, M_{\chi_0} \otimes \pi^*\eta) \cong H^*_c(G_k, R\pi_1 M_{\chi_0} \otimes \mathcal{L}_\eta),$$

from which the identity

$$\det(1 - T^{\deg(\chi)} \text{Fr}_{k(\deg(\chi))})^{-1} = \det(1 - T^{\deg(\eta)} \text{Fr}_{k(\deg(\eta))})^{-1}$$

follows for any $\chi \in [S]$. \hfill \Box

5.2. Objects with finite arithmetic tannakian groups on abelian varieties

As a non-trivial application of $\hat{L}$-functions, we will show that they lead to a characterization of objects with finite arithmetic tannakian groups on abelian varieties. This is an analogue of a result of Katz (see [68, Th. 6.2], recalled in Theorem B.2, (1)) for $G_m$, where in fact the $\hat{L}$-function appears implicitly (more precisely, where the logarithmic derivative $Td\log \hat{L}(M, T)$ appears); similar results appear in a preprint of Weissauer [112].

More generally, inspired by the formulation used by Katz, we can prove a stronger statement.

Definition 5.5 (Quasi-unipotent object). Let $G$ be a connected commutative algebraic group variety over $k$. An object $M$ of $D^b_c(G)$ is said to be quasi-unipotent if it is generically unramified and if there exists an integer $m \geq 1$ such that for any unramified character $\chi \in \hat{G}$, the eigenvalues of Frobenius on $H^0(G_k, M_{\chi})$ are roots of unity of order at most $m$.

Remark 5.6. (1) Any perverse sheaf $M$ on $G$ with $G^a_M$ finite is quasi-unipotent. Indeed, first $M$ is generically unramified by Corollary 3.37. Let then $m$ be the size of $G^a_M$. For any unramified character $\chi \in \hat{G}$, the Frobenius action on $H^0(G_k, M_{\chi})$ is “conjugate” to an element of $G^a_M$, so its eigenvalues are $m$-th roots of unity.

(2) If $M$ is a quasi-unipotent perverse sheaf on $G$, then it follows from the definition that any object of $(M)$ is also quasi-unipotent.

(3) Let $M$ be a quasi-unipotent object of $D^b_c(G)$. Let $g_0 \in G(k)$. Then the translated object $M' = [g \mapsto g g_0]^* M$ is also quasi-unipotent. Indeed, since $M'$ is canonically isomorphic to the convolution $\delta_{g_0} * M$, we obtain for any $\chi \in \hat{G}$ a canonical isomorphism

$$H^*_c(G_k, M'_{\chi}) \cong H^*_c(G_k, (\delta_{g_0})_{\chi}) \otimes H^*_c(G_k, M_{\chi}).$$

Noting that $H^*_c(G_k, (\delta_{g_0})_{\chi}) = H^*_c(G_k, (\delta_{g_0^{-1}})_{\chi})$, this shows already that $\chi$ is weakly-unramified for $M$ if and only if it is for $M'$.

If $\chi$ is weakly-unramified for $M'$, and belongs to $\hat{G}(k_n)$, then the Frobenius automorphism of $k_n$ acts on $H^0(G_k, (\delta_{g_0})_{\chi})$ by multiplication by $\chi(g_0^{-1})$, which is a root of unity of order bounded by the order of $g_0$ in $G(k)$. Since $M$ is quasi-unipotent, the eigenvalues of Frobenius on $H^0(G_k, M_{\chi})$ are roots of unity of order bounded independently of $\chi$.

Theorem 5.7. Let $A$ be an abelian variety over $k$. Let $M$ be an arithmetically semisimple perverse sheaf of weight zero in $P^a_{\text{arith}}(A)$ which is non-zero. If $M$ is quasi-unipotent, for instance if the group $G^a_M$ is finite, then $M$ is punctual.

Remark 5.8. As proved by Katz in the case of $G_m$, one may expect that the conclusion of the theorem extends to objects with finite geometric tannakian group (see [68, Th. 6.4] or Theorem B.2, (2)). We do not know how to prove this in general, but we will prove a weaker statement in Section 9.6 which turns out to be sufficient for many applications, including those of Chapter 12.
Before giving the proof, we state a useful corollary.

**Corollary 5.9.** Let $M$ be an arithmetically simple perverse sheaf of weight zero on an abelian variety $A$ over $k$ of dimension $g \geq 1$. Let $G$ be the neutral component of $G^\text{ari}_M$, and let $S$ be the support of $M$. The restriction of the standard representation of $G^\text{ari}_M$ to $G$ is irreducible, unless there exists $x \in A$ with $x \neq e$ such that $x + S = S$.

**Proof.** Let $P$ be an object of $(M)^\text{ari}$ which is a faithful representation of the finite component group $C = G^\text{ari}_M / G$. Its tannakian group is isomorphic to $C$, and hence the object $P$ is punctual according to Theorem 5.7. The points appearing in the decomposition of $P$ generate a finite subgroup $B$ of $A(\hat{k})$, and each skyscraper sheaf for $x \in B$ corresponds to a character $\chi_x$ of $G^\text{ari}_M$ trivial on $G$.

By a simple application of Frobenius reciprocity, a representation $\rho$ of $G^\text{ari}_M$ restricts to an irreducible representation of $G$ unless there exists $x \in C$ such that $x \neq e$ and $\rho \otimes \chi_x$ is isomorphic to $\rho$. In terms of perverse sheaves on $A$, this condition (for the standard representation) means that $M \otimes \rho$ is isomorphic to $M$, and implies therefore that $S + x = S$. This establishes the corollary.

We will prove Theorem 5.7 in the next two sections. In fact, since this case is somewhat easier, we will begin by assuming that the abelian variety $A$ is simple (which is in a reasonable sense the generic case) before handling the general situation. The reader may skip the first case to read directly the proof of the general result.

We first prove two lemmas that are used in both proofs.

**Lemma 5.10.** Let $R$ be a commutative ring with unit and $\lambda$ a non-archimedean valuation on $R$. Assume that $\lambda$ is complete with the topology given by $\lambda$.

Let $(\alpha_i)_{i \in I}$ be a family of elements of $R$ such that $|\alpha_i|_\lambda \leq 1$ for all $i \in I$, and let $(d_i)_{i \in I}$ be a family of positive integers such that

$$\lim_{i} d_i = +\infty,$$

where the limit is along the filter of the complements of finite subsets of $I$.

The product

$$\prod_{i \in I} (1 - \alpha_i T^{d_i})$$

converges and is non-zero for $T$ such that $|T|_\lambda < 1$.

**Proof.** Let $J \subset K$ be finite subsets of $I$. Then for $|T|_\lambda \leq 1$, we compute that

$$\left| \prod_{i \in K} (1 - \alpha_i T^{d_i}) - \prod_{i \in J} (1 - \alpha_i T^{d_i}) \right|_\lambda = \left| \prod_{i \in K \setminus J} (1 - \alpha_i T^{d_i}) \left( \prod_{i \in K \setminus J} (1 - \alpha_i T^{d_i}) - 1 \right) \right|_\lambda$$

$$\leq \left| \prod_{i \in K \setminus J} (1 - \alpha_i T^{d_i}) - 1 \right|_\lambda = \sum_{\emptyset \neq L \subset K \setminus J} (-1)^{|L|} |\sigma_L T^{d_L}|_\lambda,$$

where

$$\sigma_L = \prod_{i \in L} \alpha_i, \quad d_L = \sum_{i \in L} d_i.$$

We note that $|\sigma_L|_\lambda \leq 1$ for all $L$. Moreover, since the lower-bound

$$d_L \geq \min_{i \in I \setminus J} d_i$$

holds, the assumption that $d_i \to +\infty$ implies that for any integer $N \geq 1$, we can choose $J$ so that

$$\left| \sum_{\emptyset \neq L \subset K \setminus J} (-1)^{|L|} |\sigma_L T^{d_L}|_\lambda \right| \leq |T|^N_\lambda$$

93
for any finite set $K$ containing $J$. The absolute convergence of the product follows when $|T|_\lambda < 1$ using the Cauchy criterion. In particular, the product can only be zero if some term is zero, and this is not the case if $|T|_\lambda < 1$.

The next lemma gives basic structural information on zeros and poles of $\hat{L}(M, T)$, refining the last part of Proposition 5.2 in the case of abelian varieties.

**Definition 5.11.** Let $f \in \mathbb{Q}_\ell(X)$ be a non-zero rational function, $k$ a finite field and $r \in \mathbb{Z}$. We denote by $\text{wt}_{k,r}(f)$ the rational function
\[
\prod_{\alpha \text{ of } k\text{-weight } -r} (1 - \alpha T)^{v_\alpha(f)}
\]
where $\alpha$ runs over elements of $\mathbb{Q}_\ell$ which are $k$-Weil numbers of weight $-r$, and $v_\alpha$ is the order of $f$ at $\alpha$.

In other words (note the minus sign), the rational function $\text{wt}_{k,r}(f)$ is (up to leading terms) “the part of $f$ with zeros and poles of weight $r$”. Below, we will sometimes write $\text{wt}_r$ when the finite field $k$ is clear from context.

The definition implies that the identity
\[
\text{wt}_{k,r}(f_1 f_2) = \text{wt}_{k,r}(f_1) \text{wt}_{k,r}(f_2)
\]
holds for any rational functions $f_1$ and $f_2$.

**Proposition 5.12.** Let $M$ be a complex on an abelian variety $A$ over $k$ of dimension $g \geq 0$. Assume that $M$ is pure of weight zero and that $M_e$ has weights in $[a, b]$.

1. The poles (resp. zeros) of $\hat{L}(M, T)$ are $k$-Weil numbers. Their weights are of the form $-w - i$ for some even (resp. odd) integer $i$ with $0 \leq i \leq 2g$ and some integer $w$ with $a \leq w \leq b$.

   If there exists such a zero or pole then there exists an eigenvalue of weight $w$ on $M_e$, and the formula
   \[
   \text{wt}_{k,-w}(\hat{L}(M, T)) = \text{wt}_{k,-w}(\det(1 - T \text{Fr}_k \mid M_e))^{-1}
   \]
   holds.

2. If $M$ is an arithmetically simple perverse sheaf, and if $e$ belongs to the open set of the support of $M$ where $M$ is lisse, then the poles (resp. zeros) of $\hat{L}(M, T)$ have $k$-weights equal to $\dim \text{Supp}(M) - i$ for some integers $i$ with $0 \leq i \leq 2g$ such that
   \[
   \dim \text{Supp}(M) \equiv i \pmod{2},
   \]
   and there are poles and zeros of all these possible weights.

**Proof.** (1) By Proposition 5.2, we have
\[
\hat{L}(M, T) = \exp \left( \sum_{n \geq 1} \frac{|A(k_n)| t_M(e; k_n) T^n}{n} \right).
\]

This expression, combined with the purity of $M$ and the structure of the cohomology of $A$, shows that $\hat{L}(M, T)$ has:

(i) Poles of the form
\[
T = \frac{1}{\alpha \beta},
\]
where $\alpha$ is an eigenvalue of Frobenius on the stalk of $M$ at $e$, and $\beta$ is an eigenvalue of Frobenius on $H^i(A, \mathbb{Q}_l)$ for some even integer $i$ with $0 \leq i \leq 2g$. Since $\alpha$ is pure of some weight $w$ where $a \leq w \leq b$, and $\beta$ is of weight $i$, such a pole is a $|k|$-Weil number of weight $-w-i$.

(ii) Zeros of the form

$$T = \frac{1}{\alpha \beta},$$

where $\alpha$ is an eigenvalue of Frobenius on the stalk of $M$ at $e$, and $\beta$ is an eigenvalue of Frobenius on $H^i(A, \mathbb{Q}_l)$ for some odd integer $i$ with $1 \leq i \leq 2g-1$. As above, such a zero is a $|k|$-Weil number of weight $-w-i$ where $a \leq w \leq b$.

The precise formula for the parts of weight $-w$ follows from the above since $\beta = 1$ is the unique eigenvalue of weight $0$ on $H^1(A, \mathbb{Q}_l)$.

(2) If $M$ is an arithmetically simple perverse sheaf and $e$ is a point where $M$ is lisse, then the eigenvalues $\alpha$ above have weight $w = -\dim(\text{supp}(M))$, and there is at least one $\alpha$ since the stalk at $e$ is non-zero. Thus the poles and zeros above have weight $\dim(\text{supp}(M)) - i$. □

5.3. Perverse sheaves with finitely many ramified characters

In this section, we prove Theorem 5.7 in the case of an arithmetically semisimple perverse sheaf of weight zero such that the set of ramified characters for $M$ is finite. This applies in particular, for instance, if the abelian variety $A$ is simple, since the set of ramified characters is a finite union of tacs of $A$ (see Remark 3.27), and each tac is reduced to a single character if $A$ is simple.

Let $M$ be an arithmetically semisimple perverse sheaf of weight zero such that the set $\mathcal{S}$ of ramified characters for $M$ is finite. We assume that $M$ is quasi-unipotent and non-punctual, and we will deduce that $M$ is negligible, which will establish the theorem in the present case.

After a finite extension of $k$, we may assume that each $\chi \in \mathcal{S}$ is in $\hat{A}(k)$.

One reduces using Lemma 1.28 to the case of $M$ geometrically simple. We denote by $S$ the support of $M$ and by $r$ its dimension; we have $r \geq 1$ since $M$ is not punctual. We denote by $U$ a smooth open dense subset of $S$ such that $M$ is lisse on $U$.

Let $n \geq 1$ and let $a \in A(k_n)$. We denote $M^{(a)} = [x \mapsto x + a]^*M$, which is a simple perverse sheaf on $A(k_n)$. The stalk of $M^{(a)}$ at $e$ is canonically isomorphic to the stalk $M_a$ of $M$ at $a$. We note that the set of ramified characters for $M^{(a)}$ is also contained in $\mathcal{S}$, and that $M^{(a)}$ is quasi-unipotent (see Remark 5.6, (3)).

We then write

$$\hat{L}(M^{(a)}, T) = \hat{L}_0(M^{(a)}, T) \prod_{\chi \in \mathcal{S}} \det(1 - T \text{Fr}_k | H^*(A, M^{(a)})^{-1}$$

where

$$\hat{L}_0(M^{(a)}, T) = \prod_{\chi \notin \mathcal{S}} \det(1 - T^{\deg(\chi)} \text{Fr}_{k^{\deg(\chi)}} | H^0(A, M^{(a)})^{-1}.$$

Note that $\hat{L}_0(M^{(a)}, T)$ is a rational function since $\hat{L}(M^{(a)}, T)$ is one (Proposition 5.2).

The quasi-unipotence property of $M^{(a)}$ shows that the infinite product $\hat{L}_0(M^{(a)}, T)$ can be viewed as a formal power series in $\mathcal{O}[[T]]$ for some cyclotomic order $\mathcal{O}$. We can apply Lemma 5.10 to any non-archimedean place $\lambda$ of $\mathcal{O}$, since the eigenvalues of Frobenius on $H^0(A, M^{(a)})$ are roots of unity of bounded order for all unramified characters $\chi$. This implies that, for any non-archimedean place
\(\lambda\), the infinite product \(\hat{L}_0(M^{(a)}, T)\) converges in the disc defined by \(|T|_\chi < 1\). Taking \(\lambda\) to correspond to places above the characteristic of \(k\), this implies that the rational function \(\hat{L}_0(M^{(a)}, T)\) cannot have a zero or pole which is a \(|k|\)-Weil number of positive weight.

Suppose that \(a \in (A - S)(\bar{k})\). Then \(M^{(a)}_\lambda = 0\). Hence we deduce that
\[
1 = \prod_{\chi \in \mathcal{S}} \operatorname{wt}_r(\det(1 - T \operatorname{Fr}_k | H^r(A_\chi, M^{(a)}))).
\]

Thus, the Frobenius automorphism has no eigenvalue of weight \(-r\) acting on any of the spaces \(H^r(A_\chi, M^{(a)}_\lambda)\).

By purity, this translates to the condition
\[
H^{-r}(A_\chi, M^{(a)}_\lambda) = 0
\]
for all \(\chi \in \mathcal{S}\).

On the other hand, suppose that \(a \in U(\bar{k})\). Then \(M^{(a)}_\lambda = M_a\) is pure of weight \(-r\). From the above and Proposition 5.12, (2), we deduce that
\[
\hat{L}(M^{(a)}, T) = \prod_{\chi \in \mathcal{S}} \operatorname{wt}_r(\det(1 - T \operatorname{Fr}_k | H^r(A_\chi, M^{(a)})));
\]
and since the left-hand side is not 1, there exists (by purity again) at least one \(\chi \in \mathcal{S}\) such that
\[
H^{-r}(A_\chi, M^{(a)}_\lambda) \neq 0.
\]

If we combine these two statements, we conclude that \(S = A\). Indeed, the spaces \(H^{-r}(A_\chi, M^{(a)}_\lambda)\) are independent of \(a \in A(\bar{k})\) up to isomorphism. Hence, since there exists some \(a_0 \in U(\bar{k})\), if one of these spaces is non-zero, then no \(a \in A(\bar{k})\) can satisfy the condition required to have \(a \notin S(\bar{k})\).

Fixing again \(a_0 \in U(\bar{k})\), let \(\chi \in \mathcal{S}\) be such that
\[
H^{-r}(A_\chi, M^{(a_0)}_\lambda)
\]
is non-zero. Since \(M^{(a_0)}\) is a simple perverse sheaf supported on \(S = A\), and \(r = \dim(S) = \dim(A)\), it follows from Lemma A.15 that \(M^{(a_0)}_\chi\) is geometrically trivial. This implies that \(M\) is negligible.

### 5.4. The general case

In this section, we prove Theorem 5.7 in the general case. Thus let \(M\) be an arithmetically semisimple perverse sheaf of weight zero in \(\mathcal{P}^{\text{int}}_\text{arith}(A)\), which we assume is quasi-unipotent and not punctual. We will show that \(M\) is negligible.

It suffices to treat the case of a simple perverse sheaf \(M\) (Lemma 1.28).

We denote by \(S\) the support of \(M\) and by \(r\) its dimension; we have \(r \geq 1\) by our assumption that \(M\) is not punctual. Let \(U\) be an open dense subset of \(S\) contained in the smooth locus of \(S\) such that \(M\) is lisse on \(U\).

Let \((\mathcal{S}_i)_{i \in I}\) be a finite family of tacs such that the set of ramified characters is contained in the union \(\mathcal{S}\) of the \(\mathcal{S}_i\). After a finite extension of \(k\), we may assume that each \(\mathcal{S}_i\) is defined by a quotient morphism \(\pi_i: A \to A_i\) defined over \(k\) and a character \(\chi_i \in \hat{A}(k)\).

For any subset \(J\) of \(I\), we denote by \(\mathcal{S}_J\) the intersection of \(\mathcal{S}_i\) for \(i \in J\); this is either empty or a tac of \(A_i\), also defined over \(k\) (Lemma 1.25), in which case we denote by \(\pi_J: A \to A_J\) and \(\chi_J\) the corresponding quotient morphism and character; these are all defined over \(k\). From Lemma 1.25, it follows also that \(\ker(\pi_J)\) is the algebraic subgroup of \(A\) generated by the family of subgroups \((\ker(\pi_i))_{i \in I}\). We write \([\mathcal{S}_J]\) for the set of classes in \([\hat{A}]\) of characters in \(\mathcal{S}_J\).

96
Let $a \in \Lambda(k)$. We denote $M^{(a)} = [x \mapsto x + a]^* M$, so that the stalk $M^{(a)}_x$ is canonically isomorphic to the stalk $M_{a}$ of $M$ at $a$. The ramified characters for $M^{(a)}$ are also contained in the tac $\mathcal{J}$, and the perverse sheaf $M^{(a)}$ is quasi-unipotent (see Remark 5.6, (3)).

We define

$$\hat{L}_0(M^{(a)}, T) = \prod_{\chi \in [\mathcal{J}] - \mathcal{F}} \det(1 - T^{|\deg(\chi)\text{ Fr}_{k_{\deg(\chi)}}}| H^0(A_k, M^{(a)}_\chi))^{-1}.$$

By an application of inclusion–exclusion, we have

$$\hat{L}(M^{(a)}, T) = \hat{L}_0(M^{(a)}, T) \prod_{\emptyset \neq J \subset I} \prod_{\mathcal{J} \neq \emptyset} \det(1 - T^{|\deg(\chi)\text{ Fr}_{k_{\deg(\chi)}}}| H^*(A_k, M^{(a)}_\chi))^{(-1)^{|J|}}.$$

For any $J \subset I$ such that $\mathcal{J} \neq \emptyset$ is not empty, we denote

$$Q_J^{(a)} = R\pi_J^* M^{(a)}_{\chi_J}.$$

Proposition 5.4 implies the formula

$$(5.6) \quad \prod_{\chi \in [\mathcal{J}]} \det(1 - T^{|\deg(\chi)\text{ Fr}_{k_{\deg(\chi)}}}| H^*(A_k, M^{(a)}_\chi))^{-1} = \hat{L}(Q_J^{(a)}, T),$$

so that we can rewrite the above expression as

$$(5.7) \quad \hat{L}(M^{(a)}, T) = \hat{L}_0(M^{(a)}, T) \prod_{\emptyset \neq J \subset I} \hat{L}(Q_J^{(a)}, T)^{(-1)^{|J|+1}}.$$

By Proposition 5.2 (2), this shows in particular that $\hat{L}_0(M^{(a)}, T)$ is a rational function. The quasi-unipotence property of $M^{(a)}$ shows that the infinite product $\hat{L}_0(M^{(a)}, T)$ can be viewed as a formal power series in $\mathcal{O}[[T]]$ for some cyclotomic order $\mathcal{O}$. We can apply Lemma 5.10 to any non-archimedean place $\lambda$ of $\mathcal{O}$, since the eigenvalues of Frobenius on $H^0(A_k, M^{(a)}_\chi)$ are roots of unity of bounded order for all unramified characters $\chi$. This implies that, for any non-archimedean place $\lambda$, the infinite product $\hat{L}_0(M^{(a)}, T)$ converges in the disc defined by $|T|_\lambda < 1$. Taking $\lambda$ to correspond to places above the characteristic of $k$, this implies that the rational function $\hat{L}_0(M^{(a)}, T)$ cannot have a zero or pole which is a $|k|$-Weil number of positive weight.

Since $r \geq 1$, the formula (5.7) therefore implies the formula

$$\text{wt}_r(\hat{L}(M^{(a)}, T)) = \prod_{\emptyset \neq J \subset I} \text{wt}_r \left( \hat{L}(Q_J^{(a)}, T)^{(-1)^{|J|+1}} \right).$$

Let $J \subset I$. By proper base change, we have a canonical isomorphism

$$Q_J^{(a)} = (R\pi_J^* M^{(a)}_{\chi_J})_e \simeq H^*(\ker(\pi_J)_\kappa, M^{(a)}_{\chi_J}).$$

Since $M^{(a)}$, hence also $M^{(a)}_{\chi_J}$, is a perverse sheaf, the complex $M^{(a)}_{\chi_J}$ is concentrated in degrees between $-r$ and $r$. Its support is $S - a$, and consequently, the cohomology group

$$H^i(\ker(\pi_J)_\kappa, M^{(a)}_{\chi_J}) = H^i((\ker(\pi_J) \cap (S - a))_\kappa, M^{(a)}_{\chi_J})$$
vanishes unless $0 \leq i + r \leq 2 \dim(\ker(\pi_j) \cap (S - a))$. Since $M^a$ has weight 0, this space has weight $i$ when it is non-zero. Using the formula

$$
\hat{L}(Q_j^{(a)}, T) = \exp \left( \sum_{n \geq 1} |A_j(k_n)| t_{Q_j^{(a)}}(e; k_n) \frac{T^n}{n} \right)
$$

of Proposition 5.2, this means that

$$
\begin{align*}
\wt_r(\hat{L}(Q_j^{(a)}, T)) &= \det(1 - T \Fr_k | H^{-r}((\ker(\pi_j) \cap (S - a))_k, M_j^{(a)}))^{-1} \\
&= \det(1 - T \Fr_k | H^{-r}((a + \ker(\pi_j)) \cap S)_k, M_j)\chi_j)_{\pi_j}^{-1} \\
&= \det(1 - T \Fr_k | (R^{-r}\pi_j^* M_j)^{\pi_j(a)})^{-1} = \det(1 - T \Fr_k | (\pi_j^* R^{-r} \pi_j^* M_j)_a)^{-1}.
\end{align*}
$$

Let $X = S - U$, so that $A - X = U \cup (A - S)$. If $a \in (A - X)(k)$, the left-hand side of (5.8) is the part of weight $-r$ of

$$
\hat{L}(M^{(a)}, T) = \exp \left( \sum_{n \geq 1} |A(k_n)| t_M(a; k_n) \frac{T^n}{n} \right).
$$

Since $M_a$ is $|k|$-pure of weight $-r$ (either because $a \in U(k)$, so that $M$ is lisse and of weight $-r$ at $a$, or because $a \in (A - S)(k)$, so that $M_a$ is zero, hence pure of any weight), we deduce that the equality

$$
(5.9) \quad \det(1 - T \Fr_k | M_a) = \prod_{\emptyset \neq J \subseteq I \atop J \neq \emptyset} \det(1 - T \Fr_k | (\pi_j^* R^{-r} \pi_j^* M_j)_a)^{(-1)^{|J|+1}}
$$

holds. In particular, this gives the equality

$$
t_M(a; k) = \sum_{\emptyset \neq J \subseteq I \atop J \neq \emptyset} (-1)^{|J|+1} t_{\pi_j^* R^{-r} \pi_j^* M_j}(a; k)
$$

of values of trace functions for $a \in (A - X)(k)$.

Let $n \geq 1$. Applying this argument to the base change of $M$ to $k_n$, we see that the formula

$$
t_M(a; k_n) = \sum_{\emptyset \neq J \subseteq I \atop J \neq \emptyset} (-1)^{|J|+1} t_{\pi_j^* R^{-r} \pi_j^* M_j}(a; k_n)
$$

holds for $a \in (A - X)(k_n)$. By the injectivity of trace functions (see [87, Th.1.1.2]), this means that we have an equality

$$
(5.10) \quad M = \sum_{\emptyset \neq J \subseteq I \atop J \neq \emptyset} (-1)^{|J|+1} \pi_j^* R^{-r} \pi_j^* M_j
$$

in the Grothendieck group $K(A - X)$.

If $U = S$ (e.g. if $M$ is the extension by zero of a lisse sheaf of weight 0 placed in degree $-r$ on a smooth closed subvariety $S$, which will be the case in the applications of Theorem 5.7 in Chapter 12), then $X$ is empty, so this equality holds in $K(A)$. The right-hand side is a linear combination of negligible objects (see Example 3.5) so we deduce that $M$ is negligible by taking the Euler–Poincaré characteristic (see Corollary 3.22).

We now consider the general case. Let $j$ be the open immersion of $A - X$ in $A$. Recall that the classes of simple perverse sheaves form a basis of the $\Z$-module $K(A - X)$ (see Proposition A.22).
Thus, the equality (5.10) implies that there exists some J such that the simple perverse sheaf $j^*M$ appears in the decomposition in simple perverse sheaves of the class of $j^*N$ in $K(A - X)$, where

$$N = \pi_1^*R^{-r}\pi_j^*M_{\chi_j}.$$ 

Furthermore, this means that there exists $i \in \mathbb{Z}$ such that $j^*M$ occurs in the decomposition of the perverse sheaf $p_i^*j^*N$, since

$$j^*N = \sum_{i \in \mathbb{Z}} (-1)^i p_i^*j^*N$$

in $K(A - X)$.

The functor $j^*$ is $t$-exact (since $j$ is smooth of relative dimension 0) so that there exists a canonical isomorphism $p_i^*j^*N \rightarrow j^*p_i^*N$. Since $j^*M$ and $j^*p_i^*N$ are pure, hence geometrically semisimple, this implies the existence of an injective morphism

$$f: j^*M \rightarrow j^*p_i^*N$$

of perverse sheaves. Applying the functor $j_!^*$, which preserves injectivity (e.g., by [63, §2.17]) and satisfies $j_!^*j^* = \text{Id}$ on perverse sheaves, we deduce that there exists an injective morphism

$$j_!^*f: M \rightarrow p_i^*N.$$ 

This fact is equivalent (for pure perverse sheaves of weight 0) to the characterization of negligible objects by Weissauer [113, Th.3], since it is known that the assumption on $\mathcal{N}(M)$ is always true (Corollary 3.23). However, the proof that this is so relies on the generic vanishing theorem (Theorem 2.16), which appeals to this result of Weissauer, so this remark does not provide a different proof of this characterization.

**Remark 5.13.** A similar argument leads to a simple proof of the following fact: if $M$ is a negligible arithmetically simple simple perverse sheaf of weight zero in $\text{Parint}(A)$, and if $\mathcal{N}(M)$ is contained in a finite union of tacs of $A$, then there exists a morphism $\pi: A \rightarrow B$ of abelian varieties with $\dim(\ker(\pi)) \geq 1$, a character $\chi \in \hat{A}$ and an object $N$ of $D^b_c(B)$ such that $M$ is geometrically isomorphic to $(\pi^*N)_\chi$.

We sketch the argument nevertheless for the sake of illustration. It is relatively elementary that it suffices to prove that the isomorphism class of $M$ is invariant under translation by a non-trivial abelian subvariety (this is [113, Lemma 6]), and we will establish this fact.

To simplify matters, we assume that $S = U$ in the notation of the previous proof. Since $M$ is negligible, it is quasi-unipotent; arguing as in the previous proof, we obtain a finite decomposition

$$M = \sum_{i \in I} n_i \pi_i^*M_i$$

in $K(A)$ for some morphisms $\pi_i: A \rightarrow A_i$ with $\dim(\ker(\pi_i)) \geq 1$, some objects $M_i \in D^b_c(A_i)$ and some non-zero $n_i \in \mathbb{Z}$.

Since the classes of simple perverse sheaves form a basis of the $\mathbb{Z}$-module $K(A)$, there exists some $i \in I$ such that

$$\pi_i^*M_i = mM + \sum_{j \in J} m_j M_{i,j}$$

in $K(A)$ for some non-zero integers $m$ and $m_j$ and some simple perverse sheaves $M_{i,j}$ not isomorphic to $M$.

The isomorphism class of the complex $\pi_i^*M_i$ is invariant under translation by elements of $\ker(\pi_i)$, and a fortiori by the abelian subvariety $A'_i = \ker(\pi_i)^\circ$. We claim that this implies that the same property holds for $M$ and the other constituents $M_{i,j}$. Indeed, the $k$-valued points of $A'$ act on the finite set of isomorphism classes of the simple perverse sheaves $(M, M_{i,j})$, and thus the stabilizer of
any of them is a finite index subgroup. Since it is also an algebraic subgroup, it is equal to $A'(\tilde{k})$, and the assertion follows. Thus the isomorphism class of $M$ is invariant under translation by the non-trivial abelian variety $\ker(\pi_i)^0$, as desired.
Stratification theorems for exponential sums

The results of this section are straightforward consequences of Theorem 2.3 and Deligne’s Riemann Hypothesis. We spell them out since some of them are likely to be useful for applications to analytic number theory.

**Theorem 6.1.** Let \( k \) be a finite field, and let \( G \) be a connected commutative algebraic group of dimension \( d \) over \( k \). Let \( \ell \) be a prime distinct from the characteristic of \( k \) and let \( M \) be an object of \( D^b_c(G) \). Assume that \( M \) is semiperverse and mixed of weights \( \leq 0 \).

There exist subsets \( \mathcal{I}_d \subset \cdots \subset \mathcal{I}_0 = \hat{G} \) such that

1. For \( 0 \leq i \leq d \), the estimate
   \[
   |\mathcal{I}_i(k_n)| \ll |k|^n(d-i)
   \]
   holds for \( n \geq 1 \).
2. The set \( \mathcal{I}_d \) is empty if \( M \) belongs to the category \( \mathcal{P}_{\text{ari}}(G) \).
3. For any \( n \geq 1 \), any integer \( i \) with \( 1 \leq i \leq d \) and any \( \chi \in \hat{G}(k_n) - \mathcal{I}_i(k_n) \), the estimate
   \[
   \sum_{x \in G(k_n)} \chi(x)t_{M}(x; k_n) \ll c_u(M)|k|^{n(i-1)/2},
   \]
   holds, where the implied constant is independent of \( M \).
4. If \( G \) is either a torus or an abelian variety, then \( \mathcal{I}_i \) is a finite union of tacs of \( G \) of dimension \( \leq d - i \).
5. If \( G \) is a unipotent group, then \( \mathcal{I}_i \) is the set of closed points of a closed subvariety of dimension \( \leq d - i \) of the Serre dual \( G^\vee \).

**Proof.** For \( 1 \leq i \leq d \), let \( \mathcal{I}_i \) be the set of characters such that there exists some \( l \geq i \) with \( H^l_c(G_\bar{k}, M_\chi) \neq 0 \).

If \( \chi \in \hat{G} - \mathcal{I}_i \), then we deduce from the trace formula and the Riemann Hypothesis of Deligne, combined with Lemma 1.2, that the estimate

\[
\sum_{x \in G(k_n)} \chi(x)t_{M}(x; k_n) \ll c_u(M)|k|^{n(i-1)/2}
\]

holds for \( n \geq 1 \), which is (3). We will check that these sets also satisfy conditions (1) and (2).

Fix \( i \leq i \leq d \). For any \( l \) and \( j \), we have the perverse spectral sequence

\[
H^l_c(G_\bar{k}, p^{\mathcal{H}^l-j}(M_\chi)) \Rightarrow H^l_c(G_\bar{k}, M_\chi)
\]

(see (A.3)) so that the condition \( \chi \in \mathcal{I}_i \) implies that

\[
H^l_c(G_\bar{k}, p^{\mathcal{H}^l-j}(M_\chi)) \neq 0
\]

for some \( l \geq i \). Since \( M \) is semiperverse, so is \( M_\chi \), which means that this condition implies \( j \geq l \geq i \).
Thus, if we denote by $\mathcal{S}_{j,i}$ the sets provided by the Stratified Vanishing Theorem 2.3 applied to $\mathcal{H}^j(M)$, we have shown that

$$\mathcal{S}_i \subset \bigcup_{i \leq j \leq d} \bigcup_{i \leq l < j} \mathcal{S}_{l,j}.$$ 

The set $\mathcal{S}_{l,j}$ has character codimension at least $j$, so that $\mathcal{S}_i$ has the same property, establishing (1). Point (2) follows from the fact that

$$H^l_{\mathcal{F}}(G, N) = 0$$

for a geometrically simple perverse sheaf $N$ which is not geometrically isomorphic to $\mathcal{L}_{\chi - 1}$.

Points (4) and (5) follow from the strengthened versions of the Stratified Vanishing Theorem for tori, abelian varieties and unipotent groups, which is contained in Theorem 2.3, (4) or Proposition 2.7.

**Remark 6.2.** The following elementary estimate can also sometimes be useful. Fix a locally-closed immersion $u: G \to \mathbf{P}^m$ for some integer $m \geq 1$. Let $M$ be an $\ell$-adic perverse sheaf on $G$ that is pure of weight zero. Then by orthogonality of characters, we derive that the formula

$$\frac{1}{|G(k_n)|} \sum_{\chi \in \hat{G}(k_n)} \left| \sum_{x \in \overline{G}(k_n)} t_M(x; k_n) \chi(x) \right|^2 = \sum_{x \in \overline{G}(k_n)} |t_M(x; k_n)|^2$$

holds for $n \geq 1$. By the Riemann Hypothesis, it follows that the estimate

$$\frac{1}{|G(k_n)|} \sum_{\chi \in \hat{G}(k_n)} \left| \sum_{\chi \in \hat{G}(k_n)} t_M(x; k_n) \chi(x) \right|^2 \ll c_u(M)$$

holds for $n \geq 1$ (see Theorem 1.10). Fix then a sequence $T = (T_n)$ of positive real numbers, and let $\mathcal{S}_T \subset \hat{G}$ be the set such that $\chi \in \mathcal{S}_T(k_n)$ if and only if

$$\left| \sum_{x \in \overline{G}(k_n)} t_M(x; k_n) \chi(x) \right| > T_n.$$ 

Then we find by positivity that

$$|\mathcal{S}_T(k_n)| \ll c_u(M)|G(k_n)|T_n^{-2}.$$ 

**Corollary 6.3.** Let $k$ be a finite field, and let $G$ be a connected commutative algebraic group of dimension $d$ over $k$. Let $\ell$ be a prime distinct from the characteristic of $k$ and let $M$ be an $\ell$-adic perverse sheaf on $G$ which is pure of weight zero.

For any generic subsets $\mathcal{X}$ and $\mathcal{Y}$ of $\hat{G}$, the estimate

$$\frac{1}{|G(k_n)|} \sum_{\chi \in \mathcal{X} \setminus \mathcal{Y}(k_n)} \left| \sum_{x \in k_n} \chi(x)t_M(x; k_n) \right| \ll \frac{1}{|k|^{n/2}}$$

holds for all $n \geq 1$.

**Proof.** We may assume that $\mathcal{X} = \hat{G}$. Let $(\mathcal{S}_i)_{0 \leq i \leq d}$ be sets of characters as in Theorem 6.1. We have

$$\frac{1}{|G(k_n)|} \sum_{\chi \in \hat{G}(k_n)} \left| \sum_{x \in k_n} \chi(x)t_M(x; k_n) \right| = S_0 + \cdots + S_{d-1},$$

where for each integer $i$ with $0 \leq i < d$, we put

$$S_i = \frac{1}{|G(k_n)|} \sum_{\chi \in \mathcal{S}_i \cup (\mathcal{S}_{i+1} \cup \mathcal{Y})(k_n)} \left| \sum_{x \in k_n} \chi(x)t_M(x; k_n) \right|.$$
For \( i = 0 \), the exponential sum is \( \ll 1 \), and since \( \mathcal{Y} \) is generic, the set \( \mathcal{S}_0 - (\mathcal{S}_1 \cup \mathcal{Y}) \) has character codimension at least 1, so that

\[
\mathcal{S}_0 \ll |k|^n(-d+(d-1)) = |k|^{-n}.
\]

For \( i \leq i < d \), we have \( \mathcal{S}_i - (\mathcal{S}_{i+1} \cup \mathcal{Y}) \subset \mathcal{S}_i - \mathcal{S}_{i+1} \), so that by Theorem 6.1, (1) (for the size of \( \mathcal{S}_i \)) and (3) (estimating the character sums for \( \chi \notin \mathcal{S}_{i+1} \)), we obtain

\[
\mathcal{S}_i \ll |k|^{-nd+n((d-i)+i/2)} = |k|^{-ni/2}.
\]

\( \square \)

The next corollary states, intuitively, that for the purpose of computing the arithmetic Fourier transform of a semiperverse complex (mixed of weights \( \leq 0 \)), the contribution of any closed (suitably “transverse”) subvariety is negligible.

**Corollary 6.4.** Let \( k \) be a finite field, and let \( G \) be a connected commutative algebraic group of dimension \( d \) over \( k \). Let \( \ell \) be a prime distinct from the characteristic of \( k \) and let \( M \) be an object of \( \text{D}^b_c(G) \). Assume that \( M \) is semiperverse and mixed of weights \( \leq 0 \).

Let \( X \subset G \) be a closed subvariety of \( G \) and let \( i: X \to G \) be the corresponding closed immersion. Let \( m \geq 0 \) be an integer such that for each \( j \in \mathbb{Z} \), the estimate

\[
\dim(X \cap \text{Supp}(\mathcal{H}^j(M))) \leq \dim \text{Supp}(\mathcal{H}^j(M)) - m
\]

holds.

There exists a generic subset \( \mathcal{X} \) of \( \hat{G} \) such that the estimate

\[
\sum_{x \in X(k_n)} \chi(x)t_M(x; k_n) \ll \frac{c_u(M)}{|k_n|^{m/2}}
\]

holds for all \( n \geq 1 \) and all \( \chi \in \mathcal{X}(k_n) \).

Alternatively, we have

\[
S(M, \chi) = \sum_{x \in (G-X)(k_n)} \chi(x)t_M(x; k_n) + O(|k_n|^{-m/2}),
\]

which explains the interpretation that \( X \) does not contribute systematically to the arithmetic Fourier transform.

**Proof.** The assumption implies that the complex \( N = i! i^* M[-m][-m/2] \) is semiperverse on \( G \), since \( M \) is semiperverse and, for any \( j \in \mathbb{Z} \), the support of \( \mathcal{H}^j(N) \) is \( X \cap \text{Supp}(\mathcal{H}^{j-m}(M)) \) so that

\[
\dim(\text{Supp}(\mathcal{H}^j(N))) = \dim(X \cap \text{Supp}(\mathcal{H}^{j-m}(M))) \leq \dim(\text{Supp}(\mathcal{H}^{j-m}(M))) - m
\]

\[
\leq -(j-m) - m = -j.
\]

Moreover, the complex \( N \) has weights \( \leq 0 \). Thus we may apply Theorem 6.1 to \( N \). Let \( \mathcal{S}_0, \ldots, \mathcal{S}_d \) be the corresponding sets of characters, and let \( \mathcal{X} = \hat{G} - \mathcal{S}_1 \). This is a generic subset of \( \hat{G} \), and for \( n \geq 1 \) and \( \chi \in \mathcal{X}(k_n) \), we have

\[
(-1)^m |k_n|^{m/2} \sum_{x \in X(k_n)} \chi(x)t_M(x; k_n) = \sum_{x \in G(k_n)} \chi(x)t_N(x; k_n) \ll c_u(M),
\]

hence the result. \( \square \)
Example 6.5. Let \( \mathcal{F} \) be a non-zero lisse sheaf on \( G \), pure of weights 0, and let \( M = \mathcal{F}[d](d/2) \). We then have \( \text{Supp}(\mathcal{F}^j(M)) = \emptyset \) except when \( j = -d \), in which case the support of \( \mathcal{F}^{-d}(M) \) is \( G \). We can therefore apply the corollary to any closed subvariety \( X \) of \( G \) of codimension at least \( m \). In particular, for any closed subvariety \( X \neq G \), hence of codimension at least 1, there exists a generic set of characters \( \mathcal{X} \) for which the estimate

\[
\sum_{x \in X(k_n)} \chi(x) t_M(x; k_n) \ll \frac{c_u(M)}{|k_n|^{1/2}}
\]

holds for \( n \geq 1 \) and \( \chi \in \mathcal{X}(k_n) \).

A uniform version of the stratified vanishing theorem, as in Remark 2.4, would be especially welcome for stratification estimates, as it would lead to strong potential applications in analytic number theory (compare with the results of Fouvry and Katz [35] based on stratification for the additive Fourier transform). We state a conditional result of this kind for emphasis.

Theorem 6.6. Let \( \ell \) be a prime number. Let \( N \geq 1 \) be an integer and let \( (G, u) \) be a quasi-projective commutative group scheme over \( \mathbb{Z}[1/\ell N] \) such that, for all primes \( p \nmid \ell N \), the fiber \( G_p \) of \( G \) over \( \mathbb{F}_p \) is a connected commutative algebraic group for which Theorem 2.3 holds uniformly with respect to the complexity with respect to the locally-closed immersion of \( G_p \) deduced from \( u \).

Let \( (M_p)_{p \nmid \ell N} \) be a sequence of arithmetically semisimple sheaves on \( G_p \), pure of weight zero, such that \( c_a(M_p) \ll 1 \) for all \( p \).

For each prime \( p \), there exist subsets \( \mathcal{I}_d(F_p) \subset \cdots \subset \mathcal{I}_0(F_p) = \hat{G}_p(F_p) \) such that

1. For \( 0 \leq i \leq d \) and \( p \) prime, we have
   \( |\mathcal{I}_i(F_p)| \ll p^{d-i} \).
2. The set \( \mathcal{I}_d(F_p) \) is empty if \( M_p \) belongs to the category \( \mathcal{P}_{\text{int}}^\text{ar}(G_p) \).
3. For any prime \( p \), any integer \( i \) with \( 0 \leq i \leq d \) and any \( \chi \in \hat{G}_p(F_p) - \mathcal{I}_i(F_p) \), we have
   \[
   \sum_{x \in G(F_p)} \chi(x) t_p(x) \ll p^{(i-1)/2},
   \]
   where \( t_p \) is the trace function of \( M_p \) over \( \mathbb{F}_p \).
4. If \( G \) is a torus or an abelian variety, then the sets \( \mathcal{I}_i(F_p) \) are contained in the union of a bounded number of tacs of \( G_{\mathbb{F}_p} \) of dimension \( \leq d - i \).

Remark 6.7. For \( G = G_{\mathbb{A}}^{d_i} \), results of this kind are unconditional; see for instance [35, Th. 1.1, Th. 3.1] (note that there the sets \( \mathcal{I}_i \) are points of subschemes defined over \( \mathbb{Z} \), which we cannot hope in the general situation where \( M_p \) is allowed to vary with \( p \)).

In the case of \( G_{\mathbb{A}}^{d_i} \) (which is currently conditional), this would give (for instance) stratification and generic square-root cancellation, for sums of the type

\[
\sum_{x_1, \ldots, x_d \in \mathbb{F}_p^d} \chi_1(x_1) \cdots \chi_d(x_d) e\left( \frac{f(x_1, \ldots, x_d)}{p} \right),
\]

where \( f \in \mathbb{Z}[X_1, \ldots, X_d] \) is a polynomial and \( \chi_1, \ldots, \chi_d \) are Dirichlet characters modulo \( p \), together with an a priori algebraic description of the sets of characters where the sum has size \( \asymp p^{d/2} \).

Over finite fields, we can still derive some applications, such as the following proposition, similar to [35, Cor. 1.4] (although the vertical direction means that equidistribution is only in the finite set \( (1/p\mathbb{Z})/\mathbb{Z} \subset \mathbb{R}/\mathbb{Z} \), or equivalently modulo \( p \), as we phrase it.)
PROPOSITION 6.8. Let $p$ be the characteristic of $k$. Let $d \geq 1$ and $r \leq d$ be integers and let $f = (f_i): \mathbb{G}_m^d \to \mathbb{A}^r$ be a morphism whose image is not contained in an affine hyperplane. For a sequence $(w_n)$ such that $w_n/(|k_n|^{1/2} \log |k_n|) \to +\infty$, and for an arbitrary generator $y_n$ of $k_n^\times$, the family of residue classes

$$\text{Tr}_{k_n/F_p}(f(y_n, \ldots, y_n^d)) \pmod{p}$$

where $0 \leq v_i \leq w_n$ for all $i$, become uniformly distributed in $(\mathbb{Z}/p\mathbb{Z})^r$.

PROOF. Let $G = \mathbb{G}_m^d$ and $q = |k|$; for $n \geq 1$, denote by $\psi_n$ the additive character $x \mapsto e(\text{Tr}_{k_n/F_p}(x)/p)$ of $k_n$. Using the generator $y_n$, we can identify the group $G(k_n) = (k_n^\times)^d$ with the group $(\mathbb{Z}/(q^n-1)\mathbb{Z})^d$ and we also identify $\hat{G}(k_n)$ with $(\mathbb{Z}/(q^n-1)\mathbb{Z})^d$, the element $\beta \in (\mathbb{Z}/(q^n-1)\mathbb{Z})^d$ corresponding to the character $\chi$ such that

$$\chi(y_n, \ldots, y_n^d) = e\left(\frac{1}{q^n-1}(\beta_1 v_1 + \cdots + \beta_d v_d)\right).$$

By the Weyl Criterion, we need to prove that

$$\lim_{n \to +\infty} \frac{1}{w_n^d} \sum_{0 \leq v_i \leq w_n} \psi_n\left(\sum_{i=1}^d h_i f_i(y_n, \ldots, y_n^d)\right) = 0$$

for any $h \in (\mathbb{Z}/p\mathbb{Z})^r - \{0\}$. Detecting the interval $0 \leq v \leq w_n$ by Fourier expansion, we have to study the limit of

$$\frac{1}{w_n^d} \sum_{\chi \in \hat{G}(k_n)} \tilde{\alpha}_n(\chi) \sum_{x \in G(k_n)} \chi(x)\psi_n\left(\sum_{i=1}^d h_i f_i(x)\right)$$

where

$$\tilde{\alpha}_n(\chi) = \frac{1}{q^n-1} \sum_{0 \leq v_i \leq w_n} \chi\left(y_n, \ldots, y_n^d\right).$$

Define $g_h: G \to \mathbb{A}^1$ by

$$g_h(x) = \sum_i h_i f_i(x).$$

We can write

$$\frac{1}{w_n^d} \sum_{\chi \in \hat{G}(k_n)} \tilde{\alpha}_n(\chi) \sum_{x \in G(k_n)} \chi(x)\psi_n\left(\sum_{i=1}^r h_i f_i(x)\right) = \frac{1}{w_n^d} \sum_{\chi \in \hat{G}(k_n)} \tilde{\alpha}_n(\chi) q^{nd/2} S(M, \chi)$$

for the complex $M = g_h^* L_{\psi_1}[d](d/2)$ on $G$, which is a simple perverse sheaf, pure of weight 0, on $G$.

We apply Theorem 6.1 to $M$. Let $(\mathcal{S}_i)$ be the subsets described there. We have $\mathcal{S}_d = \emptyset$ because the image of $f$ is not contained in an affine hyperplane, which implies that $g_h$ is non-constant, and hence $M$ is non-trivial, from which the fact that it does not coincide with $L_\chi$ for any character $\chi \in \hat{G}$ follows. Moreover, we also know that each $\mathcal{S}_i$ is a finite union of tacs of $G$ of dimension $\leq d - i$.

The contribution of all $\chi \in (\mathcal{S}_0 - \mathcal{S}_1)(k_n)$ to the previous sum satisfies the bound

$$\frac{1}{w_n^d} \sum_{\chi \in (\hat{G} - \mathcal{S}_1)(k_n)} \tilde{\alpha}_n(\chi) q^{nd/2} S(M, \chi) \ll \frac{q^{nd/2}}{w_n^d} \sum_{\chi \in \hat{G}(k_n)} |\tilde{\alpha}_n(\chi)|.$$
holds for all \( n \geq 1 \), where the implied constant depends on \( d \), so that
\[
\frac{1}{w_n^d} \sum_{\chi \in (\hat{G}_{-\mathcal{Y}_1}(k_n))} \hat{\alpha}_n(\chi) q^{nd/2} S(M, \chi) \ll \left( \frac{q^{n/2} \log(q)}{w_n} \right)^d,
\]
which converges to 0 as \( n \to +\infty \) by assumption.

We now handle the remaining terms. Let \( 1 \leq j \leq d - 2 \). By Theorem 6.1, the estimate
\[
\frac{1}{w_n^d} \sum_{\chi \in (\mathcal{Y}_j - \mathcal{Y}_{j+1})(k_n)} \hat{\alpha}_n(\chi) q^{nd/2} S(M, \chi) \ll \frac{q^{n(d+j)/2}}{w_n^d} \sum_{\chi \in \mathcal{Y}_j(k_n)} |\hat{\alpha}_n(\chi)|
\]
holds for all \( n \geq 1 \). From Lemma 6.9 below and the fact that \( \mathcal{Y}_j \) is a finite union of tacs of codimension at least \( j \), we deduce that the estimate
\[
\sum_{\chi \in \mathcal{Y}_j(k_n)} |\hat{\alpha}_n(\chi)| \ll \left( \frac{w_n}{q^n} \right)^j (\log q)^d
\]
holds for \( n \geq 1 \). It follows that
\[
\frac{1}{w_n^d} \sum_{\chi \in (\mathcal{Y}_j - \mathcal{Y}_{j+1})(k_n)} \hat{\alpha}_n(\chi) q^{nd/2} S(M, \chi) \ll \frac{q^{n(d+j)/2}}{w_n^d} \left( \frac{w_n}{q^n} \right)^j (\log q)^d = \left( \frac{q^{n/2}}{w_n} \right)^{d-j} (\log q)^d.
\]
The conclusion follows. \( \square \)

**Lemma 6.9.** With notation as above, for any tac \( \mathcal{Y} \) of \( G_d^d \) of dimension \( d - j \), \( j < d \), we have
\[
\sum_{\chi \in \mathcal{Y}(k_n)} |\hat{\alpha}_n(\chi)| \ll \left( \frac{w_n}{q^n} \right)^j (\log q)^d.
\]

**Proof.** Mutatis mutandis, this is very close to [35, Lemma 9.5], in the (simpler) case where the variety \( \mathcal{Y} \) of loc. cit. is an affine hyperplane (but with the primes \( p \) replaced by the sequence \( q^n - 1 \)). Indeed, let \( f: G_d^d \to G_{d-j}^d \) and \( \chi_0 = (\chi_{0,1}, \ldots, \chi_{0,d}) \) be the morphism of tori and the character \( \chi_0 \) defining \( \mathcal{Y} \). There exists a matrix \( m = (m_{k,l}) \) of size \( d \times (d-j) \) with integral coefficients of rank \( j \) such that a character \( \eta = (\eta_1, \ldots, \eta_d) \) of \( G_d^d \) belongs to \( \mathcal{Y}(k_n) \) if and only if
\[
\prod_{l=1}^d \eta_l^{m_{k,l}} = \chi_{0,k}^{-1}
\]
fors \( 1 \leq k \leq d-j \). When we identify \( \hat{G}_m^d(k_n) \) with \( (\mathbb{Z}/(q^n - 1)\mathbb{Z})^d \), this means that \( \mathcal{Y}(k_n) \) is identified with the set of solutions \( (\xi_1, \ldots, \xi_d) \) in \( (\mathbb{Z}/(q^n - 1))^d \) of the equation
\[
\sum_{l=1}^d m_{k,l} \xi_l = y_k
\]
for some \( y_k \in (\mathbb{Z}/(q^n - 1)\mathbb{Z}) \). \( \square \)
CHAPTER 7

Generic Fourier inversion

As usual, $k$ is a finite field, with an algebraic closure $\bar{k}$ and finite extensions $k_n$ of $k$ in $\bar{k}$ of degree $n$. We fix a prime $\ell$ distinct from the characteristic of $k$.

Let $G$ be a connected commutative algebraic group over $k$. Given an object $M$ of $D^b_c(G)$, an integer $n \geq 1$ and a character $\chi \in \hat{\hat{G}}(k_n)$, we set

$$S(M, \chi) = \sum_{x \in G(k_n)} \chi(x)t_M(x; k_n).$$

For two semisimple perverse sheaves $M$ and $N$, Proposition 1.20 implies that if the arithmetic Fourier transforms of $M$ and $N$ coincide, in the sense that $S(M, \chi) = S(N, \chi)$ for any $\chi \in \hat{\hat{G}}$, then the trace functions of $M$ and $N$ coincide over $k_n$ for all $n \geq 1$, which implies that $M$ and $N$ are isomorphic (Proposition A.22; see also [91, Prop. 4.2.3] for tori).

The stratified vanishing theorem allows us to prove a statement of “generic Fourier inversion” for pure perverse sheaves, which relaxes the condition of equality of all sums $S(M, \chi)$ and $S(N, \chi)$ to a condition for a generic set of characters.

**Theorem 7.1** (Generic Fourier inversion). Let $G$ be a connected commutative algebraic group over $k$. Let $M$ and $N$ be arithmetically semisimple $\ell$-adic perverse sheaves on $G$ which are pure of weight zero.

The perverse sheaves $M_{\text{int}}$ and $N_{\text{int}}$ are arithmetically isomorphic if and only if there exists a generic set $\mathcal{X} \subset \hat{\hat{G}}$ such that $S(M, \chi) = S(N, \chi)$ for all $\chi \in \mathcal{X}$.

**Proof.** If $M_{\text{int}}$ is isomorphic to $N_{\text{int}}$, then the sums $S(M, \chi)$ and $S(N, \chi)$ coincide for a generic set of characters because $S(P, \chi)$ vanishes generically for a negligible object $P$.

To prove the converse, we may assume that $M = M_{\text{int}}$ and $N = N_{\text{int}}$, i.e., that $M$ and $N$ are objects of $\mathbf{P}_{\text{int}}(G)$. We then argue by induction on the sum $m$ of the lengths of $M$ and $N$.

If $m = 0$, then the perverse sheaves $M$ and $N$ are both zero.

Suppose now that $m \geq 1$ and that the statement holds for all pairs $(M_1, N_1)$ of perverse sheaves in $\mathbf{P}_{\text{int}}(G)$ such that the sum of the lengths of $M_1$ and $N_1$ is $\leq m - 1$. One at least of the perverse sheaves $M$ and $N$ is non-zero, and (up to exchanging $M$ and $N$) we may assume that $M$ is non-zero. Let $(Q_i)_{i \in I}$ be the simple components (without multiplicity) of the perverse sheaf $M \oplus N$, and for $i \in I$, let $\mu_M(i)$ (resp. $\mu_N(i)$) be the multiplicity of $Q_i$ in $M_{\text{int}}$ (resp. $N_{\text{int}}$).

Let $\mathcal{Y}$ be the set of Frobenius-unramified characters for the perverse sheaf

$$(M *_{\text{int}} N^\vee) \oplus (M *_{\text{int}} M^\vee),$$

viewed as an object of $(M \oplus N)^{\text{ari}}$.

For any integer $n \geq 1$, we consider the sum

$$T_n = \frac{1}{|G(k_n)|} \sum_{\chi \in \mathcal{Y}(k_n)} S(M *_{\text{int}} N^\vee, \chi).$$
Applying Corollary 4.6 after decomposing $M$ and $N$ in terms of the simple perverse sheaves $Q_i$, we obtain the formula

$$\lim_{N \to +\infty} \frac{1}{N} \sum_{n \leq N} T_n = \sum_{i \in I} \mu_M(i)\mu_N(i).$$

On the other hand, we can write

$$T_n = \frac{1}{|G(k_n)|} \sum_{\chi \in \mathcal{Y}(k_n)} S(M \ast_{\text{int}} M^\vee, \chi) + \frac{1}{|G(k_n)|} \sum_{\chi \in \mathcal{Y}(k_n)} \left( S(M \ast_{\text{int}} N^\vee, \chi) - S(M \ast_{\text{int}} M^\vee, \chi) \right)$$

for any $n \geq 1$. For $\chi$ in the generic set $\mathcal{X} \cap \mathcal{Y}$, the assumption implies that

$$S(M \ast_{\text{int}} N^\vee, \chi) = S(M \ast_{\text{int}} M^\vee, \chi).$$

Thus, using Corollary 6.3, the assumption implies that the bound

$$\frac{1}{|G(k_n)|} \sum_{\chi \in \mathcal{Y}(k_n)} \left( S(M \ast_{\text{int}} N^\vee, \chi) - S(M \ast_{\text{int}} M^\vee, \chi) \right) \ll |k_n|^{-1/2}$$

holds for $n \geq 1$. Applying Corollary 4.6 once more and comparing with the previous computation, we deduce that

$$\sum_{i \in I} \mu_M(i)\mu_N(i) = \sum_{i \in I} \mu_M(i)^2.$$

The right-hand side is $\geq 1$ since $M$ is non-zero. Hence, there exists $i$ such that $\mu_M(i)\mu_N(i) \geq 1$, which means that $Q_i$ appears with positive multiplicity in both $M$ and $N$. Removing one occurrence of $Q_i$ from $M$ and $N$, we obtain perverse sheaves $M_1$ and $N_1$ in $P_{\text{int}}(G)$ for which we can apply the induction hypothesis, so that $M_1$ is isomorphic to $N_1$, and adding the simple perverse sheaf $Q_i$ to both sides, we deduce that $M$ is isomorphic to $N$. 

**Remark 7.2.** In the case of tori, this result is related to a conditional result of Loeser [91, Prop. 4.2.5].

\[108\]
CHAPTER 8

Independence of $\ell$

We consider in this section a connected commutative algebraic group $G$ over a finite field $k$. Let $p$ be the characteristic of $k$. Since we will vary the prime $\ell \neq p$, we will indicate it in the notation. For an object $M$ of $D^b_c(G, \mathcal{Q}_\ell)$, we will now denote by $t_M(x; k_n)$ the $\mathcal{Q}_\ell$-valued trace function of $M$, and we will also specify explicitly the isomorphisms $\iota$ used to define their complex-valued analogues. In particular, we write $\hat{G}(\ell)$ for the set of $\ell$-adic characters.

We recall (see, e.g., [44, Def. 1.2] with $E = \mathcal{C}$) that if $A$ is a set of pairs $(\ell, \iota)$ consisting of a prime number $\ell$ different from the characteristic of $k$ and an isomorphism $\iota : \mathcal{Q}_\ell \to \mathcal{C}$, a family $(M_\alpha)_{\alpha \in A}$ of objects of $\text{Perv}(G, \mathcal{Q}_\ell)$ is said to be a compatible system if for any $n \geq 1$ and $x \in G(k_n)$, the complex numbers $\iota(t_M(x; k_n))$ are independent of $\alpha = (\ell, \iota) \in A$.

The question we wish to address is the following:

**QUESTION.** Suppose that we have a compatible system $(M_\alpha)_{\alpha \in A}$; to what extent are the arithmetic and geometric tannakian groups of $M_\alpha$ independent of $\alpha$?

We note that the analogue question for the monodromy groups of a compatible system of lisse sheaves on an algebraic variety $X$ over $k$ (especially a curve) has been considered in considerable depth, e.g., by Serre [107, p. 1–21], Larsen–Pink [86], Chin [19] and others.

In this section, we take a first step in our setting. We will only compare two objects, so for the remainder of this section, we let $(\ell_1, \iota_1)$ and $(\ell_2, \iota_2)$ be pairs of primes and isomorphisms $\iota_j : \mathcal{Q}_{\ell_j} \to \mathcal{C}$. For $j = 1, 2$, we fix an $\ell_j$-adic arithmetically semisimple perverse sheaf $M_j$ on $G$ which is of $\ell_j$-weight zero. We assume that $M_1$ and $M_2$ are compatible (i.e., the system with $A = \{(\ell_1, \iota_1), (\ell_2, \iota_2)\}$ is compatible).

We start with a simple lemma.

**Lemma 8.1.** For any $n \geq 1$, the map $\eta : \chi \mapsto \iota_2^{-1} \circ \iota_1 \circ \chi$ is a bijection from $\hat{G}(\ell_1)(k_n)$ to $\hat{G}(\ell_2)(k_n)$.

For any $\chi \in \hat{G}(\ell_1)$, the objects $(M_1)_\chi$ and $(M_2)_{\eta(\chi)}$ are compatible. Moreover, the set of weakly unramified characters $\chi \in \hat{G}(\ell_1)$ for $M_1$ such that $\eta(\chi)$ is weakly unramified for $M_2$ is generic.

**Proof.** This boils down to the computation

$$
\iota_1(t_{(M_1)_\chi}(x; k_n)) = \iota_1(t_{M_1}(x; k_n)\chi(N_{k_n/k}(x))) \\
= \iota_1(t_{M_1}(x; k_n))\iota_1(\chi(N_{k_n/k}(x))) \\
= \iota_2(t_{M_2}(x; k_n))\iota_2(\eta(\chi))(N_{k_n/k}(x)) = \iota_2(t_{M_2}^\eta(\chi)(x; k_n))
$$

for any $n \geq 1$ and $x \in G(k_n)$, which follows from the definitions, and the fact that $\mathcal{S}_w(M_1)$ and $\eta^{-1}(\mathcal{S}_w(M_2))$ are both generic, and hence so is their intersection in $\hat{G}(\ell_1)$.

109
We begin with a general proposition that shows that the tannakian dimensions of compatible objects, as well as the reductive rank of their arithmetic tannakian groups, and the number of connected components of these groups, are independent of \( \ell \).

**Proposition 8.2.** We continue with the notation above.

1. The tannakian dimension of \( M_1 \) and \( M_2 \) coincide and the reductive rank of the reductive groups \( G^{\text{ari}}_{M_1} \) and \( G^{\text{ari}}_{M_2} \) are the same.

2. If \( M_1 \) and \( M_2 \) are generically unramified, then the number of connected components of \( G^{\text{ari}}_{M_1} \) and \( G^{\text{ari}}_{M_2} \) are equal.

**Proof.** We use the notation of Lemma 8.1, and denote by \( \mathcal{X} \) the set of weakly unramified characters \( \chi \in \tilde{G}(\ell) \) for \( M_1 \) such that \( \eta(\chi) \) is weakly unramified for \( M_2 \); this is a generic set.

1. By Proposition 3.16, for any \( \chi \in \mathcal{X} \), the tannakian dimension of \( M_1 \) is equal to the Euler–Poincaré characteristic of \((M_1)_\chi\) and the tannakian dimension of \( M_2 \) is equal to the Euler–Poincaré characteristic of \((M_2)_\eta(\chi)\). Since \((M_1)_\chi\) and \((M_2)_\eta(\chi)\) are compatible, these Euler–Poincaré characteristics are equal (see, e.g., [100, Lemma 6.38]), so the fact that \( \mathcal{X} \) is not empty implies that the tannakian dimensions coincide.

Let \( r \) be the common tannakian dimension of \( M_1 \) and \( M_2 \). The reductive rank \( \kappa \) of \( G^{\text{ari}}_{M_1} \) can be determined as the dimension of the support of the measure \( \nu_{cp} \) on \( U_r(\mathbb{C})^d \) appearing in Theorem 4.4 (because \( \kappa \) is the dimension of the space of characteristic polynomials of \( G^{\text{ari}}_{M_1} \), see [107, p. 17]). By compatibility and Lemma 3.33, we have

\[
\nu_1(\det(1 - T \text{Fr}_{M_1,k_n}(\chi))) = \nu_2(\det(1 - T \text{Fr}_{M_2,k_n}(\eta(\chi))))
\]

for any \( \chi \in \mathcal{X}(k_n) \). Since the set \( \mathcal{X} \) is generic, we deduce from Theorem 4.4 that the reductive ranks of \( G^{\text{ari}}_{M_1} \) and \( G^{\text{ari}}_{M_2} \) are equal.

2. The key ingredient is a version of the “zero-one law” used by Serre [107, Th., p. 18] for the analogue statement for compatible systems of Galois representations over \( \mathbb{Q} \). Precisely:

**Lemma 8.3 (Zero-one law).** Let \( M \) be a generically unramified \( \ell \)-adic perverse sheaf on \( G \) of tannakian dimension \( r \), for some prime \( \ell \neq p \). For a polynomial \( f \in \mathbb{Z}[a_1, \ldots, a_r] \) and an integer \( m \geq 1 \), we denote by \( \mathcal{X}_{f,m} \) the set of weakly unramified characters \( \chi \in \tilde{G}(\ell)(M) \) such that \( \chi \in \mathcal{X}_{f,m}(k_n) \) if and only if \( f(\text{Fr}_{M,k_n}(\chi)) = 0 \), where we define \( f(g) \) for \( g \in \text{GL}_r \) by interpreting the variables \( a_i \) as the coefficients of the characteristic polynomial \( \det(T - g) \) of an element \( g \) of \( \text{GL}_r \).

An integer \( m \geq 1 \) is divisible by the number of connected components of \( G^{\text{ari}}_{M} \) if and only if for all \( f \in \mathbb{Z}[a_1, \ldots, a_r] \), the limit

\[
\lim_{N \to +\infty} \frac{1}{N} \sum_{1 \leq n \leq N} |\mathcal{X}_{f,m}(k_n)|
\]

exists and is equal to either 0 or 1.

In our situation, we have by compatibility

\[
\nu_1(f(\text{Fr}_{M_1,k_n}(\chi)^m)) = \nu_2(f(\text{Fr}_{M_2,k_n}(\eta(\chi))^{m}))
\]

for any character \( \chi \in \mathcal{X}(k_n) \) and integer \( m \geq 1 \), since \( f \) has integral coefficients. Hence, for a given \( m \), the statement of Lemma 8.3 holds for \( M_2 \) if and only if it does for \( M_1 \). The equality of the number of connected components follows by looking at the smallest \( m \geq 1 \) for which the zero-one law holds. \( \square \)
Proof of Lemma 8.3. We can follow Serre’s argument very closely.

First, if $m$ is divisible by the number of connected components, then the set $F$ of $g \in G_{M}^{\operatorname{ari}} \subset GL_r$ such that $f(g) = 0$ is a Zariski-closed conjugacy-invariant subvariety.

If $F$ does not contain the neutral component of $G_{M}^{\operatorname{ari}}$, then we claim that the set $\mathcal{X}_{f,m}$ satisfies

$$\lim_{N \to +\infty} \frac{1}{N} \sum_{1 \leq n \leq N} |\mathcal{X}_{f,m}(k_n)| = 0.$$ 

This follows from Theorem 4.11 by standard properties of convergence of probability measures and the fact that $F$ corresponds to a closed set of measure 0 in the set of conjugacy classes of a maximal compact subgroup of $G_{M}^{\operatorname{ari}}(C)$.

On the other hand, if $F$ contains the neutral component, then the limit exists and is equal to 1, since in that case $Fr_{M,k_n}(\chi)^m$ belongs to the neutral component for any unramified character $\chi$, and $M$ is assumed to be generically unramified.

Conversely, suppose that $m$ is not divisible by the number $\pi_0$ of connected components of $G_{M}^{\operatorname{ari}}$. There exists then a connected component $H$ of $G_{M}^{\operatorname{ari}}$ such that $H^m$ is not the neutral component; we can find some $n \geq 1$ and some unramified character $\chi \in \hat{G}(k_n)$ such that $Fr_{M,k_n}(\chi) \in H$, so that $Fr_{M,k_n}(\chi)^m$ is not in the neutral component. In fact, for the same reason as above, we have

$$\lim_{N \to +\infty} \frac{1}{N} \sum_{1 \leq n \leq N} \sum_{\chi \in \mathcal{X}(M)(k_n)} 1 = \frac{1}{\pi_0} > 0.$$ 

Applying [107, Lemme 1, p.17], we find an $f$ such that $\mathcal{X}_{f,m}$ has “density” different from 0 and 1 in the above sense.

Under a relatively strong assumption, we can go much further by exploiting a result of Larsen and Pink [85].

Proposition 8.4. We continue with the notation and assumptions above.

Assume furthermore that one of $M_1$ and $M_2$ is geometrically simple, and that the arithmetic tannakian group of $M_j$ is contained in the product of its neutral component with a finite central subgroup for $j = 1, 2$. Then the neutral components of the derived groups of $\iota_1(G_{M_1}^{\operatorname{ari}})$ and $\iota_2(G_{M_2}^{\operatorname{ari}})$ are isomorphic as complex semisimple groups.

Proof. By Proposition 8.2, (1), the perverse sheaves $M_1$ and $M_2$ have the same tannakian dimension, which we denote $r$. We view $G_{M_1}^{\operatorname{ari}}$ and $G_{M_2}^{\operatorname{ari}}$ as subgroups of $GL_r$ over the respective fields.

We denote by $\eta$ and $\mathcal{X}$ the bijection and generic set of Lemma 8.1.

Let $g: GL_r \to GL(V)$ be any finite-dimensional representation of $GL_r$ and let $\mu_j(g)$ be the multiplicity of the trivial representation in the restriction of $g$ to $G_{M_j}^{\operatorname{ari}}$. Let further $\Lambda$ be the character of the representation $g$ (viewed as an integral symmetric function of the eigenvalues of a matrix). Let $\mathcal{X}_j = \mathcal{X}_F(g(M_j)) \subset \hat{G}(\iota_j)$ be the set of Frobenius-unramified characters for $g(M_j)$.

By compatibility, we have

$$\iota_j(\Lambda(Fr_{M_j,k_n}(\chi))) = \operatorname{Tr}(g(\Theta_{M_j,k_n}(\chi))).$$
for any \( n \geq 1 \) and any character \( \chi_j \in \mathcal{X}_j \). Applying Theorem 4.4 to the test function \( \text{Tr}(\varrho) \), we obtain

\[
\mu_j(\varrho) = \lim_{N \to +\infty} \frac{1}{N} \sum_{1 \leq n \leq N} \frac{1}{|\mathcal{X}_j(k_n)|} \sum_{\chi \in \mathcal{X}_j(k_n)} \text{Tr}(\varrho(\varTheta_{M_j,k_n}(\chi))).
\]

On the other hand, the compatibility assumption implies that \( \varrho(M_1) \) and \( \varrho(M_2) \) are also compatible (since \( \Lambda \) is an integral symmetric function of the eigenvalues), and hence by Lemma 8.1 applied to these two perverse sheaves, we have

\[
\mu_1(\varrho(M_1,\kappa_n)) = \mu_2(\varrho(M_2,\kappa_n,\eta(\chi))))
\]

if \( \chi \in \mathcal{X}_1(k_n) \) is such that \( \eta(\chi) \in \mathcal{X}_2(k_n) \). We deduce that if \( \chi \in \mathcal{X}_1 \) is such that \( \eta(\chi) \in \mathcal{X}_2 \), then we have the equality

\[
\text{Tr}(\varrho(\varTheta_{M_1,k_n}(\chi))) = \text{Tr}(\varrho(\varTheta_{M_2,k_n}(\eta(\chi))))
\]

We do not know if the sets \( \mathcal{X}_1 \) and \( \mathcal{X}_2 \) correspond via \( \eta \) or not, but by the generic vanishing theorem, we have

\[
\lim_{N \to +\infty} \frac{1}{N} \sum_{1 \leq n \leq N} \frac{1}{|\mathcal{X}_1(k_n)|} \sum_{\chi \in (\mathcal{X}_1 - \eta^{-1}(\mathcal{X}_2))(k_n)} \text{Tr}(\varrho(\varTheta_{M_1,k_n}(\chi))) = 0
\]

since there \( \ll |k|^{n(d-1)} \) terms in the inner sum and each summand is bounded by \( \dim(V) \). There is a similar limit when we exchange \( M_1 \) and \( M_2 \), and we can combine this with (8.1) to conclude that \( \mu_1(\varrho) = \mu_2(\varrho) \).

Now we will use the assumption that either \( M_1 \) or \( M_2 \) is geometrically simple, say \( M_1 \) without loss of generality. Since this is equivalent (by the classical Schur Lemma) with the condition that \( \mu_1(\text{Ad}) = 1 \), where \( \text{Ad} \) is the adjoint representation of \( \text{GL}_r \), it follows that \( M_2 \) is also geometrically simple.

We also assumed that \( \text{G}_{\text{ari}}^{\text{M}_j} \) is contained in the product of its neutral component with a central subgroup. By Schur’s Lemma again, the central subgroup is in fact contained in the center \( Z \) of \( \text{GL}_r \), and hence \( \mu_j(\varrho) \) is also the multiplicity of the trivial representation in the restriction of \( \varrho \) to the neutral component \( \text{G}_j^0 \). Schur’s Lemma once more implies that \( \text{G}_j^0 \) is contained in \( Z \text{G}_j \), where \( \text{G}_j \) is the derived group of \( \text{G}_j^0 \). Hence, we have \( \mu_j(\varrho) = \nu_j(\varrho) \), the multiplicity of the trivial representation in the restriction of \( \varrho \) to \( \text{G}_j \). Thus \( \nu_1(\varrho) = \nu_2(\varrho) \), and since this holds for all \( \varrho \), a theorem of Larsen and Pink [85, Th.2] implies that \( G_1 \) and \( G_2 \) are isomorphic, which is the statement we wanted to prove. \( \square \)

**Remark 8.5.** (1) Proposition 8.4 applies for instance if one knows that \( \text{SL}_r \subset \text{G}_{\text{ari}}^{\text{M}_j} \subset \text{GL}_r \). As we will see in a number of examples, this is a relatively frequent occurence.

(2) Using Theorem 4.8 or Theorem 4.4, it also follows that for a general compatible system \( (M_\alpha)_{\alpha \in A} \), the image by the trace of the Haar probability measure on a maximal compact subgroup of \( \text{Ad}(\text{G}_{\text{ari}}^{\text{M}_\alpha}(\text{C})) \) is independent of \( \alpha \). Let \( \nu \) denote this common measure. Then we deduce that the following are independent of \( \alpha \):

- the property of \( \text{G}_{\text{ari}}^{\text{M}_\alpha} \) being finite, which corresponds to the fact that \( \nu \) is a finite sum of Dirac masses; if that is the case, then the order of the group is also independent of \( \alpha \), either by Proposition 8.2, or because it is the inverse of the measure of the point \( r \). Note that one cannot say anything more in general using only the measure \( \nu \), since for instance all finite groups of order \( r \) embedded in \( \text{GL}_r(\text{C}) \) by the regular representation give rise to the same image measure by the trace.
the fact that $M_\alpha$ has tannakian group containing $\text{SL}_r$, by Larsen’s Alternative (Theorem 9.4 below).
In order to determine the tannakian (or monodromy) group associated to a perverse sheaf, Katz has developed essentially two different sets of methods. The first one (see, e.g., [61, 62]) relies on local monodromy information, and applies mostly to the additive group, although there is also a weaker analogue for the multiplicative group (see [68, Ch. 16] and Corollary 3.45). However, we are not currently aware of any similar tools for other groups. The second method, expounded in [66], is much more global, and exploits the diophantine potential of the equidistribution of exponential sums to reveal properties of the underlying group. It turns out that this global method adapts very well to the tannakian framework, and this will be our fundamental tool.

We denote as usual by \( k \) a finite field, with an algebraic closure \( \overline{k} \), and finite extensions \( k_n \) of degree \( n \) in \( \overline{k} \). We fix a prime \( \ell \) different from the characteristic of \( k \).

9.1. The diophantine irreducibility criterion

We first state Katz's criterion for a perverse sheaf to be geometrically simple in terms of its trace functions.

**Proposition 9.1.** Let \( X \) be a quasi-projective algebraic variety over \( k \), and \( M \) an \( \ell \)-adic perverse sheaf on \( X \) which is pure of weight zero. Then the equality

\[
\lim_{n \to +\infty} \sum_{x \in X(k_n)} |t_M(x; k_n)|^2 = 1
\]

holds if and only if \( M \) is geometrically simple.

See [66, Th. 1.7.2 (3)] for the proof.

**Remark 9.2.** This can be seen as a version of Schur’s Lemma (compare with Corollary 4.6): intuitively, by equidistribution, the limit in the proposition should converge to the multiplicity of the trivial representation in the representation \( \text{End} (\text{Std}) \), where \( \text{Std} \) is the standard representation of the (usual) geometric monodromy group of the lisse sheaf on an open dense part of the support of \( M \) that is associated to \( M \). The classical version of Schur’s Lemma states that this multiplicity is equal to 1 if and only if the standard representation is irreducible.

9.2. Larsen’s alternative

In this section, \( r \geq 1 \) is an integer and \( G \) is a reductive algebraic subgroup of \( \text{GL}_r \) over an algebraically closed field of characteristic zero (recall that reductive groups are not required to be connected). For each integer \( m \geq 1 \), the *absolute 2m-th moment* of an algebraic representation \( V \) of \( G \) is defined as

\[
M_{2m}(G, V) = \dim (V^m \otimes (V^*)^m)^G.
\]

When \( V \) is the “standard” \( r \)-dimensional representation given by the inclusion \( G \subset \text{GL}_r \) (also denoted by Std), we will simply write \( M_{2m}(G) \).
If the base field is $C$, so that $G$ is a reductive subgroup of $GL_r(C)$, the moments can be written as integrals over a maximal compact subgroup $K$ of $G$ with Haar probability measure $\mu_K$. Namely, for all $m \geq 1$, they are given by the integral expression

\begin{equation}
M_{2m}(G) = \int_K |\text{Tr}(g)|^{2m} d\mu_K(g).
\end{equation}

We first note some elementary properties of the moments.

(1) Given a surjective homomorphism $f : H \to G$ and a representation $\varrho : G \to GL(V)$, the equality

\[ M_{2m}(H, \varrho \circ f) = M_{2m}(G, \varrho) \]

holds for all $m \geq 1$ (since $(\varrho \otimes (\varrho^\vee)^{\otimes m})^G = ((\varrho \circ f)^{\otimes m} \otimes (\varrho \circ f)^{\otimes m})^H$ by definition).

(2) For groups $G_1$ and $G_2$ with representations $V_1$ and $V_2$, the equality

\begin{equation}
M_{2m}(G_1 \times G_2, V_1 \boxtimes V_2) = M_{2m}(G_1, V_1)M_{2m}(G_2, V_2)
\end{equation}

holds for all $m \geq 1$ (this might be easiest to see using the integral expression (9.2)).

(3) If $G \subset GL(V)$, and $Z$ is a subgroup of scalar matrices in $GL(V)$, then the equality

\[ M_{2m}(G, V) = M_{2m}(ZG, V) \]

holds (because $Z$ acts trivially on the whole space $V^{\otimes m} \otimes (V^\vee)^{\otimes m}$).

(4) If there exists a $G$-invariant decomposition

\[ V^{\otimes m} = \bigoplus_i n_i V_i, \]

then the $2m$-th moment satisfies the inequality

\begin{equation}
M_{2m}(G, V) \geq \sum_i n_i^2,
\end{equation}

with equality if and only if the $V_i$ are pairwise non-isomorphic irreducible representations (see [65, 1.1.4]).

(5) If there exists a $G$-invariant decomposition

\[ \text{End}(V) = \bigoplus_i m_i W_i, \]

then the fourth moment satisfies

\begin{equation}
M_4(G, V) \geq \sum_i m_i^2,
\end{equation}

with equality if and only if the $W_i$ are pairwise non-isomorphic irreducible representations (see [65, 1.1.5]).

Since the tensor constructions involved in the definition of the moments are representations of the ambient group $GL(V)$, Theorem 4.4 immediately yields a diophantine interpretation of the moments of the arithmetic tannakian group of a perverse sheaf.

**Proposition 9.3.** Let $G$ be a connected commutative algebraic group over $k$, and let $M$ be an arithmetically semisimple $\ell$-adic perverse sheaf on $G$ which is pure of weight zero. For each character $\chi \in \hat{G}(k_n)$, consider the sum

\[ S(M, \chi) = \sum_{x \in G(k_n)} t_M(x; k_n)\chi(x). \]
Let \( \mathcal{X} = \mathcal{X}_w(M) \) be the set of weakly unramified characters for \( M \) and let \( m \geq 0 \) be an integer.

The absolute moments of \( M \), viewed as a representation of the arithmetic tannakian group \( G_{\text{ari}}^M \), satisfy the following:

\[
M_{2m}(G_{\text{ari}}^M, M) = \lim_{N \to +\infty} \frac{1}{N} \sum_{1 \leq n \leq N} \frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{X}(k_n)} |S(M, \chi)|^{2m},
\]

\[
M_{2m}(G_{\text{ari}}^M, M) \leq \liminf_{N \to +\infty} \frac{1}{N} \sum_{1 \leq n \leq N} \frac{1}{|G(k_n)|} \sum_{\chi \in G(k_n)} |S(M, \chi)|^{2m}.
\]

Moreover, if the limit

\[
\lim_{n \to +\infty} \frac{1}{|\mathcal{X}(k_n)|} \sum_{\chi \in \mathcal{X}(k_n)} |S(M, \chi)|^{2m}
\]

exists, then it is equal to the \( 2m \)-th moment \( M_{2m}(G_{\text{geo}}^M, M) \) of \( M \), viewed as a representation of the geometric tannakian group \( G_{\text{geo}}^M \), and we have

\[
M_{2m}(G_{\text{geo}}^M, M) = M_{2m}(G_{\text{ari}}^M, M).
\]

**Proof.** We use the integral expression

\[
M_{2m}(G_{\text{ari}}^M, M) = \int_K |\text{Tr}(g)|^{2m} d\mu_K(g),
\]

where \( K \subset G_{\text{ari}}^M(\mathbb{C}) \) is a maximal compact subgroup with Haar probability measure \( \mu_K \). Recall that to each weakly unramified character \( \chi \in \mathcal{X}(k_n) \) is associated the unitary conjugacy class \( \Theta_{M,k_n}(\chi) \) such that the equality \( S(M, \chi) = \text{Tr}(\Theta_{M,k_n}(\chi)) \) holds, and that these conjugacy classes become equidistributed on average as \( n \to +\infty \) by Theorem 4.4. The first formula (9.6) follows from this result applied to the test function \( g \mapsto |\text{Tr}(g)|^{2m} \).

Moreover, the inequality

\[
\frac{1}{N} \sum_{1 \leq n \leq N} \frac{1}{|G(k_n)|} \sum_{\chi \in \mathcal{X}(k_n)} |S(M, \chi)|^{2m} \leq \frac{1}{N} \sum_{1 \leq n \leq N} \frac{1}{|G(k_n)|} \sum_{\chi \in G(k_n)} |S(M, \chi)|^{2m}
\]

holds by positivity of \( |S(M, \chi)|^{2m} \). Taking the equivalence \( |G(k_n)| \sim |\mathcal{X}(k_n)| \) as \( n \to +\infty \) from the generic vanishing theorem into account, we deduce the second formula (9.7).

Finally, the last assertion follows from Proposition 4.17, applied to the representation \( g = \text{Std}^\otimes m \otimes (\text{Std}^V)^\otimes m \), and from the fact that if the limit (9.8) exists, then its value is the same as the limit in (9.6). \( \square \)

We can combine this computation with Larsen’s alternative, a remarkable criterion that ensures that a reductive subgroup \( G \subset \text{GL}_r \) is either finite or contains one of the standard classical groups, provided it has the correct fourth or eighth moment.

**Theorem 9.4 (Larsen’s alternative).** Let \( V \) be a vector space of dimension \( r \geq 2 \) over an algebraically closed field of characteristic zero and let \( G \subset \text{GL}(V) \) be a reductive algebraic subgroup. Let \( Z \) denote the center of \( \text{GL}(V) \) and \( G^0 \) the connected component of the identity of \( G \).

1. The fourth moment satisfies \( M_4(G, V) \geq 2 \). Furthermore, if \( V \) is self-dual and \( r \geq 3 \), then \( M_4(G, V) \geq 3 \).
2. If \( M_4(G, V) \leq 5 \), then the representation of \( G \) on \( V \) is irreducible.
(3) If $M_4(G, V) = 2$, then either $SL(V) \subset G$ or $G/(G \cap Z)$ is finite. If $G \cap Z$ is finite, for instance if $G$ is semisimple, then either $G^0 = SL(V)$ or $G$ is finite.

(4) Assume $r \geq 5$. If $M_4(G, V) = 2$ and $M_8(G, V) = 24$, then $SL(V) \subset G$.

(5) Assume that there exists a non-degenerate symmetric bilinear form $B$ on $V$ such that $G$ lies in $O(B)$. If $M_4(G, V) = 3$, then either $G = SO(B)$, or $G = O(B)$, or $G$ is finite. If $r$ is 2 or 4, then $G$ is not contained in $SO(B)$.

(6) Assume that there exists a non-degenerate alternating bilinear form $B$ on $V$ such that $G$ lies in $Sp(B)$. If $r \geq 4$ and $M_4(G, V) = 3$, then either $G = Sp(B)$ or $G$ is finite.

Proof. The first statement concerning the fourth moment is a straightforward consequence of the inequality (9.4). Indeed, since $V^{\otimes 2} \otimes (V^*)^{\otimes 2}$ always contains a trivial one-dimensional subrepresentation, the fourth moment can only be 1 for $V$ of dimension 1. Moreover, there is a $GL(V)$-invariant (and hence $G$-invariant) decomposition

$$V^{\otimes 2} = \text{Sym}^2 V \oplus \bigwedge^2 V,$$

where the factors are distinct and non-trivial, and of dimension $\geq 2$ if $r \geq 3$. If $V$ is self-dual, one of the two summands contains a proper one-dimensional $G$-invariant subspace, so that the fourth moment is at least 3 using (9.4) again.

The other statements concerning the fourth moment are proved by Katz in [65, Th.1.1.6]. The statement about the eighth moment was conjectured by Katz in [66, 2.3], and proved by Guralnick and Tiep in [50, Th.1.4]. Indeed, according to loc. cit., a reductive subgroup $G$ of $GL(V)$ either satisfies $M_8(G) > M_8(GL(V))$ or contains the commutator subgroup $[GL(V), GL(V)] = SL(V)$, and the eighth moment of $GL(V)$ is equal to 24 for $r \geq 4$, in view of the $GL(V)$-invariant decomposition

$$V^{\otimes 4} = \text{Sym}^4 V \oplus \bigwedge^4 V \oplus 3S^{(3,1)} V \oplus 2S^{(2,2)} V \oplus 3S^{(2,1,1)} V$$

into pairwise non-isomorphic irreducible representations (see e.g. [45, Ex.6.5]), where $S^\lambda$ denotes the Schur functor associated to a partition $\lambda$ of 4.

In practice, computing a given moment of the arithmetic tannakian group $G_{\text{arith}}$ by means of the limit (9.6) is feasible if there are sufficiently many independent variables of summation, corresponding to the characters of $G$, in comparison with the number of variables involved in the object $M$, that is, the dimension of its support. It is then possible, at least in some cases, to detect a diagonal behavior that can lead to the asymptotic formula for the moment. This limitation explains why it is difficult to apply Larsen’s alternative when $G$ is one-dimensional, but starting from two-dimensional groups it can be sometimes implemented for objects supported on curves.

Remark 9.5. (1) Using typical terminology from geometric group theory, it is convenient to summarize the third part of Theorem 9.4 by saying that if $G \subset GL(V)$ has fourth moment equal to 2, then either $G \supset SL(V)$ or $G$ is virtually central in $GL(V)$.

(2) The book [66] of Katz develops applications of Larsen’s alternative which involve sums of the type

$$S(f) = \sum_{x \in X(k)} t_1(x)t_2(f(x)),$$

for suitable trace functions $t_1$ and $t_2$ (on $X$ and some affine space $A^r$, respectively), parameterized by elements $f: X \to A^r$ of a “function space” $\mathcal{F}$. One of the conditions that are shown by Katz to ensure that the $2m$-th moment can be computed is that the evaluation maps

$$f \mapsto (f(x_1), \ldots, f(x_{2m}))$$
be surjective for distinct \(x_i\) in \(X(k)\) (see [66, §1.15, Th.1.20.2] for a precise and more general statement).

### 9.3. Sidon morphisms

**Definition 9.6** (Sidon sets and Sidon morphisms). Let \(A\) be an abelian group. A subset \(S \subset A\) is called a Sidon set if all solutions \(x_1, x_2, x_3, x_4 \in S\) of the equation \(x_1 x_2 = x_3 x_4\) satisfy \(x_1 \in \{x_3, x_4\}\).

More generally, let \(r \geq 2\) be an integer. We say that \(S\) is an \(r\)-Sidon set if all tuples \((x_i)_{1 \leq i \leq r}\) and \((y_i)_{1 \leq i \leq r}\) in \(S^r\) such that the equality
\[
x_1 \cdots x_r = y_1 \cdots y_r
\]
holds satisfy \(\{x_1, \ldots, x_r\} = \{y_1, \ldots, y_r\}\). A Sidon set is thus the same as a 2-Sidon set.

Let \(\alpha \in A\). A subset \(S \subset A\) is called an \(\alpha\)-symmetric Sidon set if \(S = \alpha S^{-1}\) and all solutions \(x_1, x_2, x_3, x_4 \in S\) of the equation \(x_1 x_2 = x_3 x_4\) satisfy \(x_1 \in \{x_3, x_4\}\) or \(x_2 = ax_1^{-1}\).

Let \(G\) be a connected commutative algebraic group over a field \(k\), and let \(s: X \to G\) be a locally-closed immersion of \(k\)-schemes. We say that \(s\) is a Sidon morphism, or that \(s(X)\) is a Sidon subvariety of \(G\) if, for any extension \(k'\) of \(k\), the subset \(s(X)(k') \subset G(k')\) is a Sidon set. We define similarly \(r\)-Sidon morphisms for any \(r \geq 2\).

Let \(i\) be an involution on \(X\) and \(a \in G\). We say that \(s\) is an \(i\)-symmetric Sidon morphism if the product morphism \((s \circ i) \cdot s: X \to G\) is a constant morphism, say equal to \(a \in G\), and if, for any extension \(k'\) of \(k\), the set \(s(X(k'))\) is an \(i\)-symmetric Sidon set in \(G(k')\).

The interest of a Sidon morphism \(X \to G\) is that it leads to computations of the fourth moment for objects \(M\) on \(G\) that are pushed from \(X\). We have two versions, depending on whether we have a Sidon morphism or a symmetric Sidon morphism.

**Proposition 9.7.** Let \(G\) be a connected commutative algebraic group over a finite field \(k\) and let \(s: X \to G\) be a closed immersion of \(k\)-schemes. Let \(N\) be a geometrically simple \(\ell\)-adic perverse sheaf on \(X\) which is pure of weight 0, so that the object \(M = s_\ast N = s_\ast N\) on \(G\) is a geometrically simple perverse sheaf on \(G\) and is pure of weight 0.

1. If \(s\) is a Sidon morphism, then the equality \(M_4(G^\text{ari}_M, M) = 2\) holds unless \(M\) has tannakian dimension \(\leq 1\).

2. If \(X\) is a curve and \(s: X \to G\) is a 4-Sidon morphism, then the equality \(M_8(G^\text{geo}_M, M) = M_8(G^\text{ari}_M, M) = 24\) holds unless \(N\) is geometrically isomorphic to \(s_\ast \mathcal{Z}_\chi[1]\) for some character \(\chi \in \hat{G}\).

**Proof.** Let \(n \geq 1\) be an integer. The formula
\[
\frac{1}{|G(k_n)|} \sum_{\chi \in \hat{G}(k_n)} |S(M, \chi)|^4 = \sum_{y_1, \ldots, y_4 \in X(k_n)} t_N(y_1, k_n) t_N(y_2, k_n) t_N(y_3, k_n) t_N(y_4, k_n)
\]
holds by orthogonality of characters. If \(s\) is a Sidon morphism, then we obtain by definition
\[
\frac{1}{|G(k_n)|} \sum_{\chi \in \hat{G}(k_n)} |S(M, \chi)|^4 = 2 \left( \sum_{y \in X(k_n)} |t(y, k_n)|^2 \right)^2.
\]
Since \(N\) is geometrically simple, the right-hand side converges to 2 as \(n \to +\infty\) by Proposition 9.1. If \(s\) is a 4-Sidon morphism, then we obtain similarly

\[
\frac{1}{|G(k_n)|} \sum_{\chi \in G(k_n)} |S(M, \chi)|^8 \sim 24 \left( \sum_{y \in X(k_n)} |t(y, k_n)|^2 \right)^2
\]

which converges to 24 for the same reason.

Using the inequality (9.7) from Proposition 9.3, we deduce that

\[
M_4(G_{\text{ari}}^\text{geo}, M) \leq 2
\]

in the setting of (1). Hence, the fourth moment is either \(\leq 1\) or equal to 2. By Theorem 9.4 (1), the former is only possible if \(M_{\text{int}}\) is of tannakian dimension \(\leq 1\).

Assume now that \(X\) is a curve and \(s\) is a 4-Sidon morphism. We apply the Riemann Hypothesis (Theorem 1.10) to the simple perverse sheaves \(s^*\mathcal{Z}_{\chi}^{-1}[1](1/2)\) (of weight 0) and to \(N\). By assumption, these are not geometrically isomorphic, and therefore the estimate

\[
S(M, \chi) = \sum_{y \in X(k_n)} \chi(s(y))t_N(y; k_n) \ll 1
\]

holds for all characters \(\chi\). We deduce then that the formula

\[
\lim_{n \to +\infty} \frac{1}{|G(k_n)|} \sum_{\chi \notin \mathcal{X}^M(M)(k_n)} |S(M, \chi)|^{2m} = 0
\]

holds for any integer \(m \geq 1\); we finally conclude from the previous computations and the last assertion of Proposition 9.3 that \(M_8(G_{\text{geo}}^\text{geo}, M) = M_8(G_{\text{ari}}^\text{geo}, M) = 24\).

We now state the version involving symmetric Sidon morphisms.

**Proposition 9.8.** Let \(G\) be a connected commutative algebraic group over a finite field \(k\). Let \(X\) be a smooth irreducible algebraic variety over \(k\) and \(i\) an involution on \(X\). Let \(s: X \to G\) be an \(i\)-symmetric Sidon morphism which is a closed immersion. Let \(\alpha\) be the constant value of the morphism \((s \circ i) \cdot s\).

Let \(N\) be a geometrically simple \(\ell\)-adic perverse sheaf on \(X\) which is pure of weight 0, so that the object \(s_\dagger N = s_i N\) on \(G\) is a geometrically simple perverse sheaf on \(G\) and is pure of weight 0.

1. If \(i^\dagger N\) is isomorphic to \(D(N)\), then we have \((s_\dagger N)^\vee = [x\alpha^{-1}]^\dagger (s_\dagger N)\), and

\[
M_4(G_{\text{ari}}^\text{geo}, s_\dagger N) = 3,
\]

unless \((s_\dagger N)_{\text{int}}\) has tannakian dimension \(\leq 2\).

2. If \(i^\dagger N\) is not isomorphic to \(D(N)\), then

\[
M_4(G_{\text{ari}}^\text{geo}, s_\dagger N) = 2,
\]

unless \((s_\dagger N)_{\text{int}}\) has tannakian dimension \(\leq 2\).

**Proof.** Let \(M = s_\dagger N\). In the situation of (1), the definition of \(\alpha\) means that there is an equality \(s \circ i = [x\alpha] \circ (\text{inv} \circ s)\). Therefore, we obtain canonical isomorphisms

\[
(9.9) \quad M^\vee = \text{inv}^\dagger(D(s_\dagger N)) = \text{inv}^\dagger((s_\dagger N)) = \text{inv}^\dagger((s \circ i)_\dagger N)
\]

\[
= \text{inv}^\dagger([x\alpha]_\dagger (\text{inv} \circ s)_\dagger N) = (\text{inv} \circ [x\alpha] \circ \text{inv})_\dagger (s_\dagger N) = [x\alpha^{-1}]^\dagger M.
\]
We go back to the general case. Arguing as in the proof of the previous proposition, we obtain the equality
\[
\frac{1}{|G(k_n)|} \sum_{\chi \in \hat{G}(k_n)} |S(M, \chi)|^4 = 2 \left( \sum_{y \in X(k_n)} |t(y, k_n)|^2 \right)^2 + \sum_{(y, z) \in X(k_n)^2} t_N(y, k_n) t_N(i(y); k_n) t_N(z, k_n) t_N(i(z); k_n)
\]
for all \( n \geq 1 \), by the definition of symmetric Sidon sets. The second sum is equal to the quantity
\[
\left| \sum_{y \in X(k_n)} t_N(y, k_n) t_N(i(y); k_n) \right|^2,
\]
which converges to 1 under the assumption (1) (using (A.5)), by Proposition 9.1, and to 0 under the assumption (2), by the Riemann Hypothesis. The result now follows as before. Thus we find that
\[
M_4(G_M^{ari}, M) \leq 3, \quad \text{resp.} \quad M_4(G_M^{ari}, M) \leq 2,
\]
in case (1) (resp. (2)), and we conclude as before from Theorem 9.4, (1). \( \square \)

**Remark 9.9.** The caveats concerning the tannakian dimension of \( s_3N \) in these statements are necessary. We will indeed see concrete examples (see Example 10.10, (1) and Remark 12.2, (1)) where the fourth moment does not coincide with the limit
\[
\lim_{n \to +\infty} \frac{1}{|G(k_n)|} \sum_{\chi \in \hat{G}(k_n)} |S(M, \chi)|^4
\]
because of the contribution of some special unramified characters.

The result of Propositions 9.7 and 9.8 will be the basis of applications in Chapters 10, 11 and 12. Here are the relevant cases of Sidon morphisms, together with some further examples.

**Proposition 9.10.** Let \( k \) be a field, not necessarily finite.

1. For any \( \alpha \in k^\times \), the embedding \( x \mapsto (x, \alpha x) \) of \( G_m \) in \( G_m \times G_a \) is a Sidon morphism.
2. Let \( C \) be a smooth projective connected algebraic curve of genus \( g \geq 2 \) over \( k \). Let \( D \) be a divisor of degree 1 on \( C \), and let \( A = \text{Jac}(C) \) be the jacobian of \( C \). The closed immersion \( s: x \mapsto x - D \) of \( C \) in \( A \) is a Sidon morphism unless \( C \) is hyperelliptic, in which case it is an \( i \)-symmetric Sidon morphism, where \( i \) is the hyperelliptic involution.
3. With notation as in the previous item, if the gonality of \( C \) is at least 5, then \( s \) is a 4-Sidon morphism.
4. Let \( d \geq 1 \) be an integer and let \( f \) be a separable polynomial of degree \( d \) over \( k \). Let \( Z \) be the set of zeros of \( f \). The closed immersion \( x \mapsto (z - x)_{z \in Z} \) of \( \mathbb{A}^1[1/f] \) in \( G_m^Z \) is a Sidon morphism if \( d \geq 2 \). It is a 4-Sidon morphism if \( d \geq 4 \).
5. Suppose that the characteristic of \( k \) is not 3. The graph \( s: x \mapsto (x, x^3) \) from \( G_a \) to \( G_a^2 \) is an \( i \)-symmetric Sidon morphism, where \( i \) is the involution \( x \mapsto -x \).

**Proof.**

1. For \( x_1, \ldots, x_4 \) in \( G_m \), the equation
\[
(x_1, \alpha x_1) \cdot (x_2, \alpha x_2) = (x_3, \alpha x_3) \cdot (x_4, \alpha x_4)
\]
in \( G_a \times G_m \) means that \( x_1 + x_2 = x_3 + x_4 \) and \( x_1 x_2 = x_3 x_4 \), which implies that \( \{x_1, x_2\} = \{x_3, x_4\} \), both sets being the solutions of the same quadratic equation.
(2) Let $x_1, \ldots, x_4$ in $C$ be solutions of

$$s(x_1) + s(x_2) = s(x_3) + s(x_4).$$

Assume $x_1 \notin \{x_3, x_4\}$. Then the equation implies the existence of a rational function on $C$ with zeros $\{x_1, x_2\}$ and poles $\{x_3, x_4\}$, which corresponds to a morphism $f : C \to \mathbb{P}^1$ of degree at most 2. This is not possible unless $C$ is hyperelliptic.

With the same notation, if $C$ is hyperelliptic with hyperelliptic involution $i$, then the uniqueness of the morphism $f : C \to \mathbb{P}^1$ of degree 2 up to automorphisms (see, e.g., [88, Rem. 4.30]) shows that $i$ exchanges the points of the fibers of $f$, or in other words, that the equalities $x_2 = i(x_1)$ and $x_4 = i(x_3)$ hold.

(3) The argument is similar: the equation

$$s(x_1) + s(x_2) + s(x_3) + s(x_4) = s(x_5) + s(x_6) + s(x_7) + s(x_8)$$

where $\{x_i\} \neq \{y_i\}$ implies the existence of a non-constant morphism $f : C \to \mathbb{P}^1$ of degree at most 4, and hence implies that $C$ has gonality at most 4.

(4) Suppose that $x_1, \ldots, x_4$ satisfy $s(x_1)s(x_2) = s(x_3)s(x_4)$. Then we get

$$(x_1 - z)(x_2 - z) = (x_3 - z)(x_4 - z)$$

for all $z \in \mathbb{Z}$, i.e., the monic polynomials $(x_1 - X)(x_2 - X)$ and $(x_3 - X)(x_4 - X)$ take the same values at the points of $Z$. By interpolation, they are equal if $|Z| = d \geq 2$. The case of the 4-Sidon property is analogous with polynomials of degree 4.

(5) Suppose that $x_1, \ldots, x_4 \in G_4^d$ satisfy

$$\begin{cases} x_1 + x_2 = x_3 + x_4 \\ x_1^3 + x_2^3 = x_3^3 + x_4^3. \end{cases}$$

If $x_2 \neq -x_1$, then these imply that

$$(x_1 + x_2)^2 - 3x_1x_2 = (x_3 + x_4)^2 - 3x_3x_4,$$

and therefore $x_1x_2 = x_3x_4$ when the characteristic is not 3. Now we conclude as in (1).

Remark 9.11. (1) Example (1) is classical: it is often attributed to Ruzsa [98], but it was pointed out by Eberhard and Manners [32] that it occurs previously in a paper of Ganley [48, p. 323], where it is attributed to Spence.

Example (5) was also indicated to us by Eberhard and Manners.

(2) There is much work in combinatorics in trying to find the “densest” possible Sidon sets; in this spirit, the analogue geometric question is to classify the Sidon morphisms $s : X \to G$ such that $\dim(X)$ is maximal. The best possible value for a given group $G$ is $\dim(X) = \lceil \frac{\dim(G)}{2} \rceil$. Can this always be achieved? For instance, does there exist a Sidon curve (not a symmetric Sidon curve) in the jacobian of a (necessarily hyperelliptic) curve of genus 2?

The result concerning jacobians of smooth projective curves can be generalized by considering either Rosenlicht’s generalized jacobians (which appear in geometric class field theory, see the book of Serre [105]), or the Picard group of certain singular curves.

Proposition 9.12. Let $k$ be a field, not necessarily finite.

(1) Let $C$ be a smooth projective connected algebraic curve of genus $g \geq 2$ over $k$ which is not hyperelliptic. Let $S$ be an effective divisor on the curve $C$. Let $U$ be the complement of the support of $S$ in $C$. Let $D$ be a divisor of degree one on $U$. Let $J_S$ be the generalized
jacobian of $C$ relative to the divisor $S$. The natural immersion $s_D: U \to J_S$ defined by $x \mapsto (x) - D$ is a Sidon morphism.

(2) Let $C$ be an irreducible projective algebraic curve over $k$ whose normalization $\tilde{C}$ has genus $g \geq 2$ and is not hyperelliptic. Let $\mathfrak{A} = \text{Pic}^0(C)$ be the Picard group scheme of $A$. Let $U \subset C$ be the non-singular locus of $C$. Let $D$ be a divisor of degree one on $U$ and $\mathcal{L} \in \mathfrak{A}(k)$ the associated invertible sheaf. The natural immersion $s_D: U \to \mathfrak{A}$ defined on invertible sheaves by $x \mapsto \mathcal{O}_C(x) \otimes \mathcal{L}^{-1}$ is a Sidon morphism.

**Proof.** This follows by the same argument as in part (2) of Proposition 9.10. Indeed, in both cases, by definition, the equation

$$s_D(x_1) + s_D(x_2) = s_D(x_3) + s_D(x_4)$$

(with $x_i \in U$) implies that there exists a morphism $f: C \to \mathbb{P}^1$ with zero divisor $(x_1) + (x_2)$ and polar divisor $(x_3) + (x_4)$. In the first case, this means that $C$ is hyperelliptic. In the second case, the composition $\tilde{C} \to C \xrightarrow{f} \mathbb{P}^1$ shows that the normalization is hyperelliptic. \qed

**Remark 9.13.** (1) Both the generalized jacobians $J_S$ and the Picard group scheme of an irreducible curve are connected commutative algebraic groups over $k$ which may involve all types of groups (unipotent groups, abelian varieties and tori).

More precisely, the following results hold:

(1) Let $C$ be a smooth projective curve of genus $g \geq 0$ over $k$ and $S$ an effective divisor on $C$. Write $S$ in the form

$$S = \sum_{x \in \text{Supp}(S)} n_x(x)$$

with $n_x \geq 1$. The generalized jacobian $J_S$ is an extension

$$0 \to L_S \to J_S \to \text{Jac}(C) \to 0$$

of the (usual) jacobian of $C$, with kernel $L_S = R_S / G_m$, where $R_S$ is isomorphic to a product

$$R_S = \prod_{x \in \text{Supp}(S)} (G_m \times V_x)$$

with $V_x$ unipotent of dimension $n_x - 1$, and with $G_m$ embedded diagonally in $R_S$ (see, e.g., [105, p. 2 and V.13, V.14]).

In particular, when $g \geq 2$, the group $J_S$ has non-trivial abelian, toric and unipotent parts as soon as the support of $S$ contains two distinct points, one of which at least has coefficient $\geq 2$.

(2) Let $C$ be an irreducible projective curve $C$ over an algebraically closed field. Let $\tilde{C} \to C$ be the normalization of $C$, and for $x \in C(k)$, define $m_x$ to be the cardinality of the fiber of $\tilde{C} \to C$ over $x$. Then $\text{Pic}^0(C)$ has dimension $\dim H^1(C, \mathcal{O}_C)$, and it is an extension

$$0 \to K_C \to \text{Pic}^0(C) \to \text{Jac}(\tilde{C}) \to 0$$

of the jacobian of the normalization $\tilde{C}$, with kernel $K_C$ which is an extension of a torus of dimension

$$\sum_{x \in C \setminus U} (m_x - 1)$$

by a unipotent group, of dimension therefore equal to

$$\dim H^1(C, \mathcal{O}_C) - g(\tilde{C}) - \sum_{x \in C \setminus U} (m_x - 1)$$
Note furthermore that these two classes of algebraic groups are closely related (e.g., any generalized Jacobian $J_S$ is the Picard group of some singular curve).

(2) Some of the other examples of Sidon morphisms in Proposition 9.10 can be interpreted in terms of generalized Jacobians. For instance, consider the curve $C = \mathbb{P}^1$ over $k$, and the effective divisor $S = (0) + 2(\infty)$, so that $U = \mathbb{P}^1 - \{0, \infty\} = G_m$. According to the above, the generalized Jacobian $J_S$ is isomorphic to $G = (G_m \times G_m \times G_a)/G_m^\Delta$, where the subgroup $G_m^\Delta$ is embedded diagonally by $x \mapsto (x, (x, 0))$. An isomorphism $\varphi: J_S \to G$ is given as follows: given a divisor $E$ of degree 0 on $\mathbb{P}^1$, represent it as the divisor of a rational function $g: \mathbb{P}^1 \to \mathbb{P}^1$, and let

$$\varphi(E) = (g(0), (g(\infty), \frac{g' \cdot (\infty)}{g}(\infty)))$$

(this can be checked from the description in [105, p. 2 and V.13, V.14]). The morphism $G \to G_m \times G_a$ given by $(x, (y, a)) \mapsto (xy^{-1}, a)$ is an isomorphism, and using to identify $G$ with $G_m \times G_a$, the formula above becomes $\varphi(E) = (\frac{g(1)}{g(\infty)}, \frac{g'(\infty)}{g}(\infty))$.

Consider first the morphism $U = G_m \to J_S$ defined using the divisor $D = (1)$. Then the morphism $s_D: x \mapsto (x) - (1)$ is given by $s_D(x) = (x, 1 - x)$ (take $g(t) = (t - x)/(t - 1)$ to compute $\varphi((x) - (1))$). This is a Sidon morphism, the argument for this being identical with Proposition 9.10, (1).

In fact, minor tweaks to this example lead to a Sidon morphism $s_D: G_m \to G_m \times G_a$ which is exactly the diagonal morphism $x \mapsto (x, x)$ that appears in loc. cit. It suffices to use the isomorphism $\tilde{\varphi}: J_S \to G_m \times G_a$ such that $\tilde{\varphi}(E) = (\frac{g(1)}{g(\infty)}, \frac{g'(\infty)}{g}(\infty))$ (i.e., compose $\varphi$ with the automorphism $(x, y) \mapsto (x, -y)$), and to change the divisor $D$ to $D = D + D'$ with $D'$ the divisor (of degree 0) of the function $(T^2 + T - 1)/(T^2 - 1)$. Indeed, since $\tilde{\varphi}(D') = (1, -1)$, we find that

$$\tilde{\varphi}((x) - (D + D')) = (x, x - 1) - (1, -1) = (x, x - 1) + (1, 1) = (x, x).$$

### 9.4. Gabber’s torus trick

We discuss here another criterion to have a large tannakian group that also involves Sidon sets, but in a very different manner from their appearance in the previous sections. This criterion is difficult to apply for an individual object, but it leads to simple specialization results.

We use a version of Gabber’s “torus trick” (see [62, Th.1.0]). The following statement is specialized to the case of $\text{SL}_r$ and written in the language of compact Lie groups.

**Theorem 9.14 (Gabber).** Let $V$ be a finite-dimensional complex vector space of dimension $r \geq 1$, and let $G$ be a connected semisimple compact subgroup of $\text{GL}(V)$ that acts irreducibly on $V$. Let $D$ be the subgroup consisting of the elements of $\text{GL}(V)$ that are diagonal with respect to some basis, and let $\chi_1, \ldots, \chi_r$ be the characters $D \to \mathbb{C}^\times$ giving the coefficients of the elements of $D$.

Let $A \subset D$ be a subgroup of the normalizer of $G$ in $\text{GL}(V)$. Let $S \subset \hat{A}$ be the subset of the group of characters of $A$ given by the restrictions to $A$ of the diagonal characters $\chi_i$. If $|S| = r$ and $S$ is a Sidon set in $\hat{A}$, then $G = \text{SU}(V)$.

**Remark 9.15.** Properly speaking, Gabber’s original result implies here that $G$ contains a maximal torus of $\text{SU}(V)$, and the fact that $G$ is semisimple and connected then implies that $G$ is $\text{SU}(V)$ (see, e.g., [12, p. 36, prop. 13]).

---

1 Recall that the group is $G_m \times G_a$. 

124
We emphasize that the subgroup \( A \) can be arbitrary: it may be finite, and need not be closed.

We can then deduce the following criterion.

**Proposition 9.16.** Let \( G \) be a connected commutative algebraic group over the finite field \( k \).
Let \( M \) be a simple perverse sheaf on \( G \) which is pure of weight 0 and of tannakian dimension \( r \geq 1 \).
Assume that \( M \) is generically unramified.

The geometric tannakian group \( G_{\text{geo}}^M \) contains \( \text{SL}_r \) if and only there exists an unramified character \( \chi \in \hat{G}(k_n) \) for some integer \( n \geq 1 \) such that the eigenvalues of \( \Theta_{M,k_n}(\chi) \) are distinct and form a Sidon set in \( C^\times \).

**Proof.** Suppose that \( G_{\text{geo}}^M \) contains \( \text{SL}_r \). Let \( U \subset \text{SU}_r(C) \) be the set of matrices whose eigenvalues are distinct and form a Sidon set in \( C^\times \). This is an open set (for the Lie group topology), so that equidistribution implies

\[
\liminf_{N \to +\infty} \frac{1}{N} \sum_{1 \leq n \leq N} \frac{1}{|G(k_n)|} \sum_{\Theta_{M,k_n}(\chi) \in U} 1 > 0,
\]

and hence there exists \( n \geq 1 \) and \( \chi \in \hat{G}(k_n) \) such that \( \Theta_{M,k_n}(\chi) \in U \).

Conversely, if an unramified character \( \chi \in \hat{G}(k_n) \) exists with \( \Theta_{M,k_n}(\chi) \in U \), then we can apply Theorem 9.14 to the group \( A \) generated by a fixed element in the conjugacy class \( \Theta_{M,k_n}(\chi) \), and to the neutral component of the geometric tannakian group of \( M \) (which is normalized by \( G_{\text{ari}}^M \)), since \( G_{\text{geo}}^M \) is normal in \( G_{\text{ari}}^M \) by Proposition 3.38 and its neutral component is a characteristic subgroup.

In general, we do not have robust methods to check the existence of a character with the desired properties. However, we may combine this with a specialization argument.

**Proposition 9.17.** Let \( G \) be a connected commutative algebraic group over the finite field \( k \).
Let \( M \) be a simple perverse sheaf on \( G \) which is pure of weight 0 and of tannakian dimension \( r \geq 1 \).
Assume that \( M \) is generically unramified. Let \( f: G \to H \) be a morphism of commutative algebraic groups over \( k \).

Suppose that the object \( N = Rf_!M \) is a geometrically simple perverse sheaf on \( H \) that is pure of weight 0, and suppose that \( \chi \circ f \) is unramified for \( M \) for \( \chi \) unramified for \( N \).

If the geometric tannakian group \( G_{\text{geo}}^N \) contains \( \text{SL}_r \), then \( G_{\text{geo}}^M \) contains \( \text{SL}_r \).

**Proof.** By Proposition 9.16, the assumption implies that there exists a character \( \chi \in \hat{H}(k_n) \) of \( H \) unramified for \( N \) for which \( \Theta_{N,k_n}(\chi) \) has distinct eigenvalues forming a Sidon set. Since \( \Theta_{M,k_n}(\chi \circ f) \) has the same characteristic polynomial, the character \( \chi \circ f \in \hat{G}(k_n) \) has the same property; by Proposition 9.16 again, it follows that \( G_{\text{geo}}^M \) contains \( \text{SL}_r \).

\[ \square \]

### 9.5. Recognition criteria for \( E_6 \)

We include here a criterion of Krämer to recognize the exceptional group \( E_6 \) in one of its 27-dimensional faithful representations (we always mean by \( E_6 \) the simply-connected form).

**Proposition 9.18 (Krämer).** Let \( G \) be a connected semisimple linear algebraic group over \( \overline{Q}_\ell \) or \( C \) and \( \varrho \) an irreducible faithful 27-dimensional representation of \( G \). If the 729-dimensional representation \( \text{End}(\varrho) \) of \( G \) contains an irreducible 78-dimensional subrepresentation, then \( G \) is isomorphic to the exceptional group \( E_6 \) and \( \varrho \) is one of its two fundamental 27-dimensional representations.

125
See [82, Lemma 4] for the proof. We will apply this in Section 12.2, although somewhat differently than we use Larsen’s Alternative. The following criterion is closer to the spirit of the latter, and might have interesting applications (see again Section 12.2 for an attempt).

**Proposition 9.19.** Let \( G \) be a connected semisimple linear algebraic group over \( \overline{\mathbb{Q}}_\ell \) or \( \mathbb{C} \), and let \( \varrho \) be a faithful representation of \( G \) of dimension 27. Then \( G \) is isomorphic to the exceptional group \( E_6 \) and \( \varrho \) to one of the two fundamental 27-dimensional representations of \( G \) if and only if \( M_4(G, \varrho) = 3 \) and \( \varrho \) is not self-dual.

**Proof.** Suppose first that \( G = E_6 \) and \( \varrho \) is one of its fundamental representations of dimension 27. These representations are not self-dual (see [10, Th. 2, p. 151] and [10, Pl. V, p. 260]), we see that the dimensions of the irreducible representations of \( E_6 \) that may possibly occur in the 729-dimensional representation on \( \text{End}(\varrho) \) are 1, 27, 78, 351, 650. We know that the trivial representation appears once in \( \text{End}(\varrho) \), and that the 78-dimensional adjoint representation \( \text{Ad} \) appears at least once. But the equation

\[
729 - 79 = 650 = 27a + 78b + 351c + 650d
\]

has the unique non-negative integral solution \((a, b, c, d) = (0, 0, 0, 1)\) (looking modulo 3, it becomes \( d \equiv 1 \pmod{3} \)). So we must have an isomorphism

\[
\text{End}(\varrho) \simeq 1 \oplus \text{Ad} \oplus \varrho_{650},
\]

where \( \varrho_{650} \) has dimension 650, and hence the fourth moment \( M_4(E_6, \varrho) \) is equal to 3. (This is also noted without proof by Katz [65, Rem. 1.2.3].)

We now prove the converse, and assume that \( M_4(G, \varrho) = 3 \) and \( \varrho \) is not self-dual. Since the fourth moment is \( \leq 5 \), the representation \( \varrho \) is irreducible (Theorem 9.4, (1)). Now let

\[
G_1 \times \cdots \times G_k \rightarrow G \xrightarrow{\varrho} \text{GL}_{27}
\]

be the representation obtained from the decomposition of the algebraic universal covering of \( G \) in product of almost simple groups. This composition decomposes as an external tensor product

\[
\varrho_1 \boxtimes \cdots \boxtimes \varrho_k
\]

of irreducible representations of \( G_i \). We then have

\[
3 = M_4(G, \varrho) = \prod_{i=1}^k M_4(G_i, \varrho_i)
\]

by (9.3). The condition \( M_4(G_i, \varrho_i) = 1 \) is impossible (since it implies that \( \text{dim}(\varrho_i) = 1 \), and hence \( \varrho_i \) would be trivial and this contradicts the faithfulness assumption), so we have a single factor \( G_1 \).

The representation \( \varrho_1 \) is not self-dual, which implies that the root system of \( G_1 \) (and hence of \( G \)) can only be of type \( E_6 \), or \( A_l \) for \( l \geq 2 \) or \( D_l \) with \( l \geq 3 \) odd (see, e.g. [11, p. 132, prop. 12], combined with the fact that the longest element of the Weyl group acts by \( -\text{Id} \) for the other simple root systems).

The groups of type \( A_l \) with \( l \geq 2 \) which have a 27-dimensional irreducible representation are of type \( A_2 \) (the representation with highest weight \( 2\varpi_1 + 2\varpi_2 \), in the standard notation of Bourbaki) or \( A_{26} \) (the standard representation). In the first case, the representation is actually self-dual, and in the second case, the fourth moment is equal to 2, so these are excluded (in particular, groups of type \( D_3 = A_2 \) are also excluded).

Let \( l \geq 5 \) be an odd integer. The representations of groups of type \( D_l \) which are not self-dual and have smallest possible dimension are the half-spin representations of dimension \( 2^{l-1} \) (see [11, p. 210]). Thus only \( D_5 \) could possibly give rise to a representation of dimension 27; but one can
check that there is no representation of this dimension of a group of type $D_5$ (e.g., because of the Weyl Dimension Formula, see [11, Th. 2, p. 151]).

We conclude that the group $G_1$ must be $E_6$; since its 27-dimensional representations are faithful, the projection $G_1 \to G$ is an isomorphism. □

**Remark 9.20.** This criterion shows that it may happen that the fourth moment $M_4(G, V)$ of a representation of a group $G$ is equal to 3, but the representation $V$ is not self-dual.

### 9.6. Finiteness of tannakian groups on abelian varieties

The following result strengthens Theorem 5.7 in situations when one can apply Larsen’s Alternative to the fourth moment on abelian varieties.

**Proposition 9.21.** Let $M$ be a geometrically simple perverse sheaf of weight zero on a simple abelian variety $A$ over $k$. Let $d$ be the tannakian dimension of $M$. If the group $G_{\text{ari}} M/(Z \cap G_{\text{ari}} M)$ is finite, then the object $\text{End}(M)$ in $P_{\text{int}}(G)$ is punctual and the fourth moment of $G_{\text{ari}} M$ is equal to $d^2$.

**Proof.** We observe that $G_{\text{ari}} M/(Z \cap G_{\text{ari}} M)$ is the arithmetic tannakian group of the arithmetically semisimple object $\text{End}(M)$, and apply Theorem 5.7 to obtain the first conclusion.

In particular, this implies that $\text{End}(M)$ is a direct sum of characters. From (9.4), applied to a decomposition in sum of characters, it follows that

$$M_4(G_{\text{ari}} M) \geq d^2.$$

On the other hand, let $K$ be a maximal compact subgroup of $G_{\text{ari}} M(C)$, and $\mu$ its Haar probability measure. By (9.2) and Schur’s Lemma, we derive the inequality

$$M_4(G_{\text{ari}} M) = \int_K |\text{Tr}(g)|^4 d\mu(g) \leq d^2 \int_K |\text{Tr}(g)|^2 d\mu(g) = d^2,$$

which concludes the proof. □

**Remark 9.22.** There may exist irreducible subgroups $G$ of $GL(V)$ with fourth moment equal to $\dim(V)^2$. Indeed, this is the case, for instance, of any group which has the property that all irreducible representations with trivial central character have dimension 1, since only such representations can appear in the decomposition of $\text{End}(V)$. A concrete example is given by finite Heisenberg groups (see, e.g., [51] for the relevant facts).
CHAPTER 10

The product of the additive and the multiplicative groups

10.1. Introduction

In this chapter, we consider what is perhaps the simplest case of our equidistribution results beyond those of the additive group and the multiplicative group, namely the case of \( G = \mathbb{G}_m \times \mathbb{G}_a \). Concretely, this means that we are looking at the distribution of two-parameter exponential sums of the type

\[
\frac{1}{p} \sum_{(x,y) \in \mathbb{F}_p^2 \times \mathbb{F}_p} \chi(x) e\left(\frac{ay}{p}\right) t(x,y),
\]

where \( p \) is a prime number, \( \chi \) a complex-valued multiplicative character of the finite field \( \mathbb{F}_p \), and the function \( t \) is a trace function on \( \mathbb{G}_m \times \mathbb{G}_a \) over \( \mathbb{F}_p \). In practice, we mostly consider the analogues over extensions of \( \mathbb{F}_p \) of degree \( n \to +\infty \), but we will also discuss an horizontal statement in Corollary 10.14.

Throughout this chapter, we denote by \( k \) a finite field with an algebraic closure \( \overline{k} \), and by \( \ell \) a prime different from the characteristic of \( k \). We also fix a non-trivial additive character \( \psi : k \to \mathbb{Q}_\ell^\times \). For every \( n \geq 1 \), we define \( \psi_n = \psi \circ \text{Tr}_{k_n/k} \), a non-trivial additive character of the extension \( k_n \) of \( k \) of degree \( n \) in \( \overline{k} \).

We always denote by \( G \) the group \( \mathbb{G}_m \times \mathbb{G}_a \), and we will denote by \( p_1 \) and \( p_2 \) the projections \( G \to \mathbb{G}_m \) and \( G \to \mathbb{G}_a \). For any \( n \geq 1 \) and any pair \((\chi,a)\) of an \( \ell \)-adic character of \( k_n^\times \) and an element of \( k_n \), we will sometimes denote by \( \langle \chi,a \rangle \) the character \((x,y) \mapsto \chi(x)\psi_n(ay)\) of \( G(k_n) \), and by \( \mathcal{L}_{\chi,a} \) the corresponding \( \ell \)-adic character sheaf.

We first state the specialization of Theorem 4.8 to this case, showing that there is always some equidistribution statement for the sums (10.1) in the vertical direction. Theorem 10.1. Let \( M \) be an arithmetically semisimple \( \ell \)-adic perverse sheaf on \( \mathbb{G}_m \times \mathbb{G}_a \) over \( k \), with trace function over \( k_n \) denoted \( t(x,y;k_n) \). Assume that \( M \) is pure of weight zero.

There exist an integer \( r \geq 0 \) and a reductive subgroup \( G \subset \text{GL}_r \) such that the sums

\[
S_n(\chi,a) = \sum_{(x,y) \in k_n^\times \times k_n} \chi(x)\psi_n(ay)t(x,y;k_n),
\]

where \((a,\chi)\) are pairs of an element of \( k_n \) and a multiplicative character of \( k_n^\times \), become equidistributed on average as \( n \to +\infty \), with limit measure the image under the trace of the Haar probability measure on a maximal compact subgroup of \( G(\mathbb{C}) \).

With \( G = \mathbb{G}_m \times \mathbb{G}_a \) and \( G = \mathbb{G}_M \), this is Theorem 4.8 for the object \( M \).

The remainder of this chapter will be dedicated to the exploration of special examples. We consider in particular examples where the object \( M \) (and hence the trace function in (10.1)) is supported on the “diagonal” \( y = x \). Larsen’s Alternative will allow us to prove, with surprisingly
little computation, that in this case the group $G$ in Theorem 10.1 is always essentially as large as possible.

More precisely, we first define $\Delta: G_m \to G_m \times G_a$ to be the diagonal embedding $x \mapsto (x, x)$; this is a closed immersion. Define the diagonal in $G_m \times G_a$ to be the image of $\Delta$.

For any morphism $\lambda: G_m \to G$, for an integer $n \geq 1$ and a pair $(\chi, a) \in \hat{G}_m(k_n) \times k_n$, we denote by $L^\lambda_{x,a}$ the sheaf $\lambda_*(L_{x} \otimes j^* L_{\psi(a)})$ on $G_{\hat{k}}$, where $j: G_m \to G_a$ is the open immersion.

**Theorem 10.2.** With notation as in Theorem 10.1, suppose that the input object $M$ is geometrically simple and supported on the diagonal. Suppose that $M$ is not punctual and not geometrically isomorphic to $L_{a,b}^{\chi}[1](1/2)$ for some $(\eta, b) \in \hat{G}(k_n)$. Then the integer $r$ is $\geq 2$ and the group $G$ contains $SL_r$.

We will see that we can in fact fairly often show that $G = GL_r$, and in that setting the sums

$$S_n(\chi, a) = \sum_{x \in k_n^*} \chi(x)\psi_n(ax)t_M(x, x; k_n)$$

are both well-known examples of their respective theories, and their distribution properties are as follows:

- If $\chi$ is the trivial character, we have Kloosterman sums, which are equidistributed with respect to the Sato-Tate measure, that is, to the image of the Haar probability measure on the space of conjugacy classes of $SU_2(\mathbb{C})$; this reflects the fact that the geometric and arithmetic monodromy groups for the $\ell$-adic Fourier transform of the extension by zero of $L_{\psi(x^{-1})}$ are both equal to $SL_2$, by work of Katz [61, Thm. 11.1].

- If the characteristic $p$ of $k$ is odd and $\chi$ is the character of order 2, then we have Salié sums, whose arithmetic monodromy group is a finite subgroup of $SL_2$, isomorphic to a semi-direct product of $\mathbb{F}_p^\times$ and $\mathbb{Z}/2\mathbb{Z}$ (this can be deduced from [62, Cor. 8.9.2], which shows that the corresponding sheaf is Kummer-induced). The finiteness of the group reflects the fact that Salié sums can be computed elementarily (see, e.g., [13, p. 288, Exerc. 50]), and is also an analogue of the fact that Bessel functions with half-integral index are elementary functions (see, e.g., [13, p. 269, Exerc. 20]).

- If $p \geq 7$ and $\chi$ is fixed, but $\chi^2$ is non-trivial, then the neutral component of the geometric monodromy group is $SL_2$, but its determinant is not trivial, and more precisely has order equal to the order of $\chi^2$; see [62, Th. 8.11.3, Lemma 8.11.6].

- If instead we fix $a \in \mathbb{F}_p^\times$ and vary the multiplicative character $\chi$, then the geometric tannakian group (which coincides with the one associated by Katz’s theory in [68], see
Appendix B) contains $\text{SL}_2$ for all $a$ (because the tannakian group is a subgroup of $\text{GL}_2$, and is Lie-irreducible by [68, Cor. 8.3]). If $a = -1$, then the arithmetic and geometric tannakian groups are equal to $\text{SL}_2$ (this is the case of the Evans sums in [68, Th. 14.2]). In general, the tannakian determinant is geometrically isomorphic to a punctual sheaf at $a = -1$ (so its Mellin transform is proportional to $\chi \mapsto \chi(\alpha)$).

- If $a = 0$ and we vary $\chi$, we have Gauss sums; the arithmetic and tannakian groups are equal to $\text{GL}_1$.

The relation with Theorem 10.1 is the following: we are considering the field field $k$, and the perverse sheaf $\mathcal{M}$ of weight zero is $\mathcal{M} = \Delta^* \mathcal{L}[1](1/2)$, where $\mathcal{L}$ is the lisse sheaf $\mathcal{L} = \mathcal{L}_{\psi(x-1)}$ of rank one; it is geometrically simple, and perverse since $\Delta$ is a closed immersion (Corollary A.8). The group $G$ of Theorem 10.1 is then $\text{GL}_2$ (as follows from Theorem 10.2).

Note that when we specialize to a fixed character $\chi$ or a fixed $a$, we obtain a monodromy group or a tannakian group that is a subgroup of $G$ (as seems natural), which has the following property: the identity component of the derived group $G'$ is independent of $\chi$ (resp. $a$), except for a finite exceptional set. In fact, the exceptional set for fixed $\chi$ contains only the Legendre character (if $p$ is odd), and the exceptional set for fixed $a$ contains only $a = 0$.

Note also that when we vary $\chi$ for a fixed, only the neutral component of the identity of the geometric tannakian group is independent of $\chi$, but the tannakian group is usually not connected.

Finally, observe that here none of the “specialized” geometric tannakian groups for either $G_a$ or $G_m$ coincides with the geometric tannakian group $G = \text{GL}_2$. However, in an intuitive sense, the collection of all of them “generate” this group.

We expect these phenomena to be very general, and we will consider such questions in greater generality in later works.

**Remark 10.4.** (1) Theorem 10.2 applies for instance to one-variable exponential sums of the form

$$\frac{1}{\sqrt{|k|}} \sum_{x \in k^\times} \chi(x) \eta(g(x)) \psi(ax + f(x))$$

for suitable polynomials $f$ and $g$ and for a multiplicative character $\eta$.

It is worth noting that, even if we are only interested in the distribution of these one-variable sums (and not in the more general sums allowed by Theorem 10.1 with a two-variable trace function), the *proof* of Theorem 10.1, passing through the tannakian machinery, requires the consideration of objects supported on all of $G_m \times G_a$, simply because the convolution of two objects on $G_m \times G_a$ that are supported on the diagonal $\Delta$ will be supported on the product set $\Delta \cdot \Delta = G_m \times G_a$.

(2) Remark 9.13, (2), suggests a different interpretation of Theorem 10.2. Indeed, using this remark, we can view $G_m \times G_a$ as a generalized jacobian of $C = \mathbb{P}^1$ and the diagonal morphism $G_m \to G_m \times G_a$ as a morphism of the type $x \mapsto (x) - (D)$ for a suitable divisor $D$ on $G_m$. For a perverse sheaf of weight zero on $G_m$, we have the arithmetic Mellin transform

$$\chi \mapsto \sum_{x \in k_m^\times} t_M(x; k_n) \chi(x)$$

as in the work of Katz, which may have a variety of tannakian groups (see [68, Ch. 14 to 27] for examples involving for instance $\text{SL}_n$, $\text{GL}_n$, $\text{O}_2$, $\text{SO}_2$, $\text{Sp}_2$ and $G_2$). Then the further operation
of twisting by an additive character $\psi$ leads to the sums
\[(\chi, \psi) \mapsto \sum_{x \in k^*} t_M(x; k_n) \chi(x) \psi(x)\]
which correspond to the diagonal object $\Delta_* M$ on the generalized jacobian $G_m \times G_a$. The theorem is then, analytically, an instance of the common situation where twisting an exponential sum by a generic additive character leads to “more random” exponential sums (here, replacing a potentially complicated tannakian group on $G_m$ by one that in almost all cases contains the special linear group).

Example 10.5. The following case of two-variable equidistribution has been studied “by hand” by Kowalski and Nikeghbali [80, §4.1, Th. 11]. Let $d > 5$ be a fixed integer, and consider the sums
\[S(\chi, a) = \frac{1}{\sqrt{|k|}} \sum_{t \in k} \chi(t^d - dt - a)\]
where the character $\chi$ is extended by $\chi(0) = 0$ if $\chi$ is non-trivial and $\chi(0) = 1$ if $\chi$ is trivial.

We can express these sums as Mellin transforms, namely
\[S(\chi, a) = \sum_{x \in k^*} \sum_{y \in k} \hat{S}(x, y) \chi(x) \psi(ay)\]
where
\[\hat{S}(x, y) = \frac{1}{|G(k)|} \sum_{\langle \chi, a \rangle \in \hat{G}(k)} \chi(x) \psi(-ay) S(\chi, a).\]
We compute then
\[\hat{S}(x, y) = \frac{1}{\sqrt{|k|}} \frac{1}{|G(k)|} \sum_{t \in k} \sum_{a \in k} \chi(x) \psi(-ay) \sum_{t \in k} \chi(t^d - dt - a)\]
\[= \frac{1}{\sqrt{|k|}} \frac{1}{|G(k)|} \sum_{t \in k} \sum_{a \in k} \psi(-ay) \sum_{t \in k} \chi(x) \chi(t^d - dt - a)\]
\[= \frac{1}{|k|^{3/2}} \sum_{t \in k, a \in k} \psi(-ay) = \frac{1}{|k|^{3/2}} \sum_{t \in k} \psi(-y(t^d - dt - x)).\]

Note that this trace function is not of diagonal type. It was proved however in [80] that when $|k| \to +\infty$ (including the horizontal case where $k = F_p$ with $p \to +\infty$), the sums $S(\chi, a)$ become equidistributed like the trace of random matrices in the unitary group $U_{d-1}(C)$. This was done by applying Deligne’s equidistribution theorem, and the computation of the relevant monodromy group by Katz, for each fixed $\chi$, and then averaging over $\chi$.

It would be interesting to recover this result directly from Theorem 10.1 (with $G = GL_{d-1}$), but it is not obvious how to do so: the reader can check that the computation of the fourth moment, for instance, is not at all straightforward.

10.2. Tannakian group for diagonal objects

We first compute the tannakian dimension $r$ for a perverse sheaf on $G = G_m \times G_a$ which is supported on the diagonal.

Lemma 10.6. Let $M = \Delta_*(\mathcal{M})[1]$ for some geometrically irreducible middle extension sheaf $\mathcal{M}$ on $G_m$.
(1) The tannakian dimension \( r \) of the object \( M \) is given by the formula
\[
\begin{align*}
(10.2) \quad r &= \sum_\lambda \max(0, \lambda - 1) + \sum_{x \in k^*} \left( \text{swan}_x(\mathcal{M}) + \text{drop}_x(\mathcal{M}) \right) + \text{rank}(\mathcal{M}) + \text{swan}_0(\mathcal{M}),
\end{align*}
\]
where \( \lambda \) runs over the breaks of \( \mathcal{M} \) at infinity, in the sense of [61, Ch.1], counted with multiplicity.

(2) We have \( r = 1 \) if and only if \( M = \mathcal{L}_{\eta,b}^\Delta[1] \) for some \((\eta, b) \in \hat{G}\).

(3) For all but finitely many \( a \in \bar{k} \), the tannakian dimension of \( M_a = p_{1,a} M \otimes j^* \mathcal{L}_{\psi(ax)} \) on \( G_{m,k(a)} \) is equal to \( r \).

**Proof.** (1) By Proposition 3.16, it is enough to determine the “generic” value of the dimension of the cohomology space
\[
H^0_c(G_k, M \otimes p_1^* \mathcal{L}_{\chi} \otimes p_2^* \mathcal{L}_{\psi(ax)})
\]
as \( \chi \) varies in \( \hat{G}_m \) and \( a \) in \( \bar{k} \). We have a canonical isomorphism
\[
H^0_c(G_k, M \otimes p_1^* \mathcal{L}_{\chi} \otimes p_2^* \mathcal{L}_{\psi(ax)}) = H^1_c(G_{m,\bar{k}}, \mathcal{M} \otimes \mathcal{L}_{\chi} \otimes \mathcal{L}_{\psi(ax)}),
\]
If \( \chi \) is non-trivial, this space is also isomorphic to
\[
H^1_c(A^1_{\bar{k}}, j^* (\mathcal{M} \otimes \mathcal{L}_{\chi}) \otimes \mathcal{L}_{\psi(ax)}),
\]
where \( j : G_m \to A^1 \) is the open immersion.

For all but at most one value of \( \chi \), the sheaf \( j^* (\mathcal{M} \otimes \mathcal{L}_{\chi}) \) is a Fourier sheaf in the sense of [62, (7.3.5)] (i.e., a middle extension sheaf \( \mathcal{F} \) such that Deligne’s Fourier transform is also a middle extension sheaf). Hence, the space \( H^1_c(A^1_{\bar{k}}, j^* (\mathcal{M} \otimes \mathcal{L}_{\chi}) \otimes \mathcal{L}_{\psi(ax)}) \) is the stalk at \( a \) of the Fourier transform of \( j^* (\mathcal{M} \otimes \mathcal{L}_{\chi}) \), and its generic value \( r_\chi \) as \( a \) varies in \( \bar{k} \) is computed in [62, Lemma 7.3.9, (2)], namely
\[
r_\chi = \sum_\lambda \max(0, \lambda - 1) + \sum_{x \in \bar{k}} \left( \text{swan}_x(j^* (\mathcal{M} \otimes \mathcal{L}_{\chi})) + \text{drop}_x(j^* (\mathcal{M} \otimes \mathcal{L}_{\chi})) \right),
\]
where \( \lambda \) runs over the breaks at \( \infty \) of \( j^* (\mathcal{M} \otimes \mathcal{L}_{\chi}) \), counted with multiplicity. Since \( \mathcal{L}_{\chi} \) is lisse on \( G_m \), the formulas
\[
\text{swan}_x(j^* (\mathcal{M} \otimes \mathcal{L}_{\chi})) = \text{swan}_x(\mathcal{M}) \quad \text{drop}_x(j^* (\mathcal{M} \otimes \mathcal{L}_{\chi})) = \text{drop}_x(\mathcal{M})
\]
hold for any \( x \in \bar{k}^* \). Since \( \mathcal{L}_{\chi} \) is tamely ramified at 0 for \( \chi \) non-trivial, we have
\[
\text{swan}_0(j^* (\mathcal{M} \otimes \mathcal{L}_{\chi})) = \text{swan}_0(\mathcal{M}) \quad \text{drop}_0(j^* (\mathcal{M} \otimes \mathcal{L}_{\chi})) = \text{rank}(\mathcal{M})
\]
for \( \chi \) non-trivial, which leads to \((10.2)\).

(2) Since \( \text{rank}(\mathcal{M}) \geq 1 \), and all terms in the sum \((10.2)\) are non-negative, we deduce that the condition \( r = 1 \) may hold only if \( \mathcal{M} \) has rank 1 and \( \mathcal{M} \) is lisse on \( G_m \), tame at 0, and has (unique) break at most 1 at \( \infty \). Twisting by a suitable Kummer sheaf, we may then assume that \( \mathcal{M} \) is lisse on \( A^1 \), and it must then be geometrically isomorphic to an Artin–Schreier sheaf, which by untwisting implies that \( M \) is geometrically isomorphic to some \( \mathcal{L}_{\eta,b}^\Delta \).

(3) For the object \( M_a = \mathcal{M}[1] \otimes j^* \mathcal{L}_{\psi(ax)} \) on \( G_{m,k(a)} \), the tannakian dimension is its compactly-supported Euler–Poincaré characteristic, which is equal to
\[
(10.3) \quad r_a = \text{swan}_0(\mathcal{M} \otimes j^* \mathcal{L}_{\psi(ax)}) + \text{swan}_\infty(\mathcal{M} \otimes j^* \mathcal{L}_{\psi(ax)}) + \sum_{x \in \bar{k}^*} \left( \text{swan}_x(\mathcal{M} \otimes j^* \mathcal{L}_{\psi(ax)}) + \text{drop}_x(\mathcal{M} \otimes j^* \mathcal{L}_{\psi(ax)}) \right)
\]
(see (C.12)). Since \( \mathcal{L}_{\psi(ax)} \) is lisse on \( G_a \), the formulas
\[
\text{swan}_x (\mathcal{M} \otimes j^* \mathcal{L}_{\psi(ax)}) = \text{swan}_x (\mathcal{M})
\]
\[
\text{drop}_x (\mathcal{M} \otimes j^* \mathcal{L}_{\psi(ax)})) = \text{drop}_x (\mathcal{M})
\]
hold for \( x \in \bar{k} \).

Assume that \( a \neq 0 \). Let \( \lambda \) be a break of \( \mathcal{M} \) at infinity, and \( V_\lambda \) the corresponding break-space. Then
\[
V_\lambda \otimes \mathcal{L}_{\psi(ax)} \text{ is a subspace of the } \mu \text{-break-space } W_\mu \text{ of } \mathcal{M} \otimes j^* \mathcal{L}_{\psi(ax)} \text{ where }
\]
\[
\mu = \begin{cases} 
1 & \text{if } \lambda < 1 \\
1 & \text{if } \lambda = 1 \text{ and } \mathcal{L}_{\psi(-ax)} \text{ does not occur in } V_\lambda \\
\lambda & \text{if } \lambda > 1.
\end{cases}
\]
Thus, for all but finitely many \( a \), we have
\[
\text{swan}_\infty (\mathcal{M} \otimes j^* \mathcal{L}_{\psi(ax)}) = \sum_\mu \mu \dim W_\mu = \sum_\lambda \dim V_\lambda + \sum_{\lambda > 1} (\lambda - 1) \dim V_\lambda
\]
\[
= \text{rank}(\mathcal{M}) + \sum_\lambda \max(0, \lambda - 1),
\]
which leads to \( r_a = r \) by comparing (10.3) with (10.2).

\[\square\]

**Remark 10.7.** We will classify all objects of tannakian dimension 1 in Section 10.4, and the diagonal objects of tannakian dimension 2 in Section 10.3.

We continue with a lemma to exclude finite tannakian groups in the diagonal situation.

**Lemma 10.8.** Let \( C \subset G = G_m \times G_a \) be a line given by \( y = \alpha x \) where \( \alpha \in k^\times \).

Let \( M \) be a geometrically simple perverse sheaf on \( G_m \times G_a \) supported on \( C \) and of weight zero. Assume that the arithmetic tannakian group \( G \) of \( M \) is finite. Then \( M \) is punctual.

**Proof.** The assumption implies that \( M \) is generically unramified by Corollary 3.37.

We assume that \( M \) is not punctual to get a contradiction. Then \( M \) is, up to twist and shift, the pushforward to \( G \) of the middle extension sheaf \( M_1 \) on \( G_m \cong C \).

For all \( a \), we denote \( \mathcal{M}_a = \mathcal{M} \otimes \mathcal{L}_{\psi(ax)} \), and we view \( M_a = \mathcal{M}_a[1](1/2) \) as a perverse sheaf on \( G_m \).

Since the set of unramified characters is generic, there exists \( n \geq 1 \) and \( a \in k^\times \) such that for all but finitely many \( \chi \in \hat{G}_m \), the character \( \langle \chi, a \rangle \) is unramified for \( M \). The action of the Frobenius automorphism of \( k_n \) on the space
\[
H_c^0(G, \mathcal{M} \otimes \mathcal{L}_{\chi,a}) = H_c^0(G_m, M_a \otimes \mathcal{L}_{\chi})
\]
is then by assumption of finite order bounded independently of \( \chi \). The corresponding unitary Frobenius elements \( \Theta_{M_a,k/m}(\chi) \), for \( m \geq 1 \), are then dense in a maximal compact subgroup \( K \) of the complex points of the arithmetic tannakian group of \( M_a \) by Corollary 4.14. It follows that \( K \), and hence also \( G_M \), is a finite group since a compact real Lie group has no non-trivial small subgroups. By Katz’s results on finite tannakian groups (see Theorem B.2), this would imply that the perverse sheaf \( M_a \) is punctual, which is a contradiction.

\[\square\]

We will now prove a slightly more general statement than Theorem 10.2.
Theorem 10.9. Let $\lambda: G_m \to G_m \times G_a$ be the closed embedding $\lambda(x) = (x, \alpha x)$ for some $\alpha \in k^\times$ and let $C$ be its image.

Let $M$ be a geometrically simple perverse sheaf on $G_m \times G_a$ supported on $C$ and of weight zero. Assume that $M$ is not punctual, and that $M$ is not geometrically isomorphic to $L_{\eta,b}^{\lambda}[1](1/2)$ for some $\langle \eta, b \rangle \in \hat{G}(k)$.

Let $r \geq 0$ be the tannakian dimension of $M$ and denote $G = G_{\ari} \subset \text{GL}_r$.

We then have $r \geq 2$, the group $G$ contains $\text{SL}_r$ and the standard representation of $G$ in $\text{GL}_r$ is not self-dual.

Note that the last item implies in particular that $G$ cannot be equal to $\text{SL}_2$ or $\pm \text{SL}_2$.

Proof. We may assume that $\alpha = 1$. We will apply Larsen’s Alternative. The closed immersion $\lambda$ is a Sidon morphism (Proposition 9.10, (1)), and therefore we have $M_4(\mathbb{G}) = 2$ by Proposition 9.7, unless the tannakian dimension $r$ is $\leq 1$.

From Lemma 10.6, the latter case can only occur if either $M$ is punctual, or if $M$ is geometrically isomorphic to some perverse sheaf $L_{\lambda}^{\eta, b}[1](1/2)$. Thus, the tannakian dimension is at least 2 under our assumptions.

Our assumptions therefore imply that $M_4(\mathbb{G}) = 2$. By Larsen’s Alternative (Theorem 9.4, (3)), it follows that either $G$ contains $\text{SL}_r$, or $G/G \cap Z$ is finite, where $Z \subset \text{GL}_r$ is the group of scalar matrices. We must show that this second case actually does not arise. We proceed by contradiction, assuming therefore that $G/G \cap Z$ is finite.

The intersection $G \cap Z$ is either finite or equal to $Z$. In the first case, the group $G$ would be finite, so that the object $M$ would be punctual by Lemma 10.8, which contradicts our assumptions.

So we are left with the case $G \cap Z = Z$. The object $\text{End}(M)$ of $\langle M \rangle_{\ari}$ has tannakian group $G/G \cap Z$ is finite. In particular, this object is generically unramified (Corollary 3.37). It follows that there exists a generic set $\mathcal{S} \subset \hat{G}$ with the property that the sums $S(\text{End}(M), \langle \chi, a \rangle) = |S(M, \langle \chi, a \rangle)|^2$ take only finitely many values as $\langle \chi, a \rangle$ varies in $\mathcal{S}$.

Let $n \geq 1$. For all but a bounded number of $a \in k_n$, this implies that the perverse sheaf $M_a = p_{1,*} M \otimes L_{\psi(ax)}$ on $G_{m,k_n}$ (which is geometrically simple and of weight 0 since the restriction of $p_1$ to $C$ is an isomorphism) has the property that $S(\text{End}(M_a), \chi) = |S(M_a, \chi)|^2 = |S(M, \langle \chi, a \rangle)|^2$ take only finitely many values as $\chi \in \hat{G}_{m,k_n}$ varies. By equidistribution, this is only possible if the arithmetic tannakian group of the object $\text{End}(M_a) \in \langle M_a \rangle_{\ari}$ on $G_{m,k_n}$ is finite. By Theorem B.2, this implies that $\text{End}(M_a)$ is punctual, say

$$\text{End}(M_a) = \bigoplus_{a \in S_a} n(a,s) \gamma_{a,s}^{\deg} \otimes \delta_s$$

for a subset $S_a \subset k^\times$, integers $n(a,s) \geq 1$ and unitary scalars $\gamma_{a,s}$. For all but finitely many $a \in \bar{k}$, we know also from Lemma 10.6, (3) that

$$r^2 = \dim \text{End}(M) = \dim \text{End}(M_a) = \sum_{a \in S_a} n(a,s).$$
Since all $\chi \in \hat{G}(k_n)$ are unramified for $\text{End}(M)$, we compute

$$\frac{1}{|G_m(k_n)|} \sum_{\chi \in G_m(k_n)} |S(M, \chi)|^4 = \frac{1}{|G_m(k_n)|} \sum_{\chi \in G_m(k_n)} |S(\text{End}(M), \chi)|^2$$

$$= \frac{1}{|G_m(k_n)|} \sum_{\chi \in G_m(k_n)} \left| \sum_{s \in S_a} n(a, s)\chi(s) \right|^2 = \sum_{s \in S_a} n(a, s)^2 \geq r^2.$$

Averaging over $a \in k_n$, then letting $n \to +\infty$, it follows that $M_4(G) \geq r^2 \geq 4$, which is a contradiction.

Finally, we note that the tannakian dual of $M$ is supported on the image of the diagonal under the inversion map of $G_m \times G_a$, namely on the hyperbola

$$\{(x^{-1}, -x) \mid x \in G_m\} \subseteq G_m \times G_a.$$

Since this is not a translate of the diagonal, the tannakian dual of $M$ cannot be geometrically isomorphic to $M$. □

Example 10.10. (1) Suppose that $M = L_{\eta,b}^A \otimes [1](1/2)$ for some $(\eta, b) \in \hat{G}(k)$, which corresponds to the case excluded in Theorem 10.9. For $n \geq 1$, denote by $\eta_n$ the character $\eta \circ N_{k_n/k}$ of $k_n^\times$. Then the sums $S_n(\chi, a)$ are Gauss sums, namely

$$S_n(\chi, a) = \frac{1}{|k|^{n/2}} \sum_{x \in k_n^\times} (\chi\eta_n)(x)\psi_n((a + b)x) = \frac{1}{|k|^{n/2}} (\overline{\chi\eta_n})(a + b)\tau(\chi\eta_n, \psi_n)$$

where, for any $\xi \in \hat{G}_m(k_n)$ and additive character $\Psi$ of $k_n$, we denote by

$$\tau(\xi, \Psi) = \sum_{x \in k_n^\times} \xi(x)\Psi(x)$$

the Gauss sum.

The equidistribution properties of the Gauss sums are well-known (see for instance [61, Th. 9.5]), and one deduces easily that the arithmetic tannakian group of $M$ is equal to $\text{GL}_1$. The fourth moment of all sums $S_n(\chi, a)$ converges to 2, as we saw in the previous proof, but the single contribution to the fourth moment of the (ramified) character $\langle \eta^{-1}, -b \rangle$ is $(|k_n| - 1)^3/|k_n|^4 \to 1$. (See Proposition 10.17 for the classification of objects of tannakian dimension 1 in general.)

(2) With the notation of the proof of Theorem 10.9, assume that $\mathcal{M} = \mathcal{X} \ell_{2,\psi}$ is the Kloosterman sheaf of rank 2 on $G_m$ (normalized to have weight 0 as a lisse sheaf; see (B.2)) associated to $\psi$.

The object $\mathcal{M} \otimes [1](1/2)$ has tannakian dimension 1 and geometric tannakian group equal to $\text{GL}_1$ as a $G_m$-object (since it is a hypergeometric sheaf, see Theorem B.4). On the other hand, the object $M = \Delta \mathcal{M} \otimes [1](1/2)$ on $G$ has tannakian dimension 2, and arithmetic tannakian group $\text{GL}_2$ by Lemma 10.6 and Theorem 10.9.

We compute the corresponding exponential sums to see the concrete meaning of the theorem in this case. For $n \geq 1$ and $\langle \chi, a \rangle \in \hat{G}(k_n)$, we have the formula

$$S_n(\chi, a) = \frac{1}{|k_n|} \sum_{x \in k_n^\times} \left( \sum_{y \in k_n^\times} \psi_n(xy + 1/y) \right) \chi(x)\psi_n(ax)$$

$$= \frac{1}{|k_n|} \sum_{y \in k_n^\times} \psi_n(1/y) \sum_{x \in k^\times} \psi_n((a + y)x)\chi(x).$$
For $\chi$ non-trivial, extended by $\chi(0) = 0$, this is equal to

$$S_n(\chi, a) = \frac{\tau(\chi, \psi_n)}{|k_n|} \sum_{y \in k_n^\times} \chi(a + y)\psi_n(1/y).$$

In order to complete the determination of the tannakian group in the situation of Theorem 10.9, we need to compute the tannakian determinant of $M$. There are various tools to do this:

1. one can attempt to compare the tannakian determinant for $M$ (supported on a line) with those on $G_m$, which can often be computed using the results of Katz [68];

2. one can use the relation between the tannakian determinant at $(\chi, a)$ and the determinant of Frobenius acting on the cohomology group $H^0_k(G_k, M_{(\chi, a)})$. The latter determinant may often be computed using the theory of local epsilon factors of Deligne and Laumon (see Appendix C). We will not give explicit examples here, but we perform a computation of this kind in Chapter 11 (see Proposition 11.10).

As an example of the first approach, we have for instance the following criterion:

**Proposition 10.11.** Let $C \subset G = G_m \times G_a$ be a line defined by $y = \alpha x$ where $\alpha \in k^\times$. Let $M$ be a geometrically simple perverse sheaf on $G_m \times G_a$ supported on $C$ and of weight zero. Assume that $M$ is not punctual, and that the restriction of $M$ to $C$ is not geometrically isomorphic to $L_{\eta,b}[1](1/2)$ for some multiplicative character $\eta$ and some $b$. Let $r \geq 0$ be the tannakian dimension of $M$.

Suppose that for all but finitely many $a$, the tannakian determinant of $p_{1,*} M_{(1,a)}$ on $G_m$ is geometrically of infinite order. Then we have $G = GL_r$.

**Proof.** Since $G$ contains $SL_r$, it suffices to prove that the determinant of $G$ is arithmetically of infinite order.

Since $p_1 : C \to G_m$ is an isomorphism, it follows that for any $a \in G_a$, the object $N_a = p_{1,*} M_{(1,a)}$ on $G_m$ is a perverse sheaf, and is arithmetically semisimple and pure of weight 0.

We claim that the assumption implies that the determinants of $\Theta_{M,k_n}(\langle \chi, a \rangle)$ are equidistributed on average on the unit circle, where $\langle \chi, a \rangle$ vary among Frobenius-unramified classes for the determinant. Indeed, denoting $\mathcal{X}$ this set of characters, we have for any non-zero integer $h \in \mathbb{Z}$ the relation

$$\frac{1}{|G(k_n)|} \sum_{\langle \chi, a \rangle \in \mathcal{X}(k_n)} \det(\Theta_{M,k_n}(\langle \chi, a \rangle))^h = \frac{1}{|k_n|} \sum_{a \in k_n} \frac{1}{|k_n^\times|} \sum_{\chi \in G_m(k_n)} \det(\Theta_{N_a,k_n}(\chi))^h.$$

The contribution of those finitely many $a$ such that $N_a$ has geometrically finite-order determinant tends to 0. For the other values of $a$, we have

$$\lim_{N \to +\infty} \frac{1}{N} \sum_{n \in \mathbb{N}} \frac{1}{|k_n^\times|} \sum_{\chi \in G_m(k_n)} \sum_{\langle \chi, a \rangle \in \mathcal{X}(k_n)} \det(\Theta_{N_a,k_n}(\chi))^h = 0$$

by equidistribution, in fact uniformly with respect to $a$ since the complexity of $\det(N_a)$ is bounded independently of $a$. We deduce that

$$\lim_{N \to +\infty} \frac{1}{N} \sum_{n \in \mathbb{N}} \frac{1}{|k_n|} \sum_{a \in k_n} \frac{1}{|k_n^\times|} \sum_{\chi \in G_m(k_n)} \sum_{\langle \chi, a \rangle \in \mathcal{X}(k_n)} \det(\Theta_{N_a,k_n}(\chi))^h = 0,$$
which proves the claim.

But by Theorem 4.4, the determinants of $\Theta_{M,k_n}(\langle \chi, a \rangle)$ are known to be equidistributed on average on the subset of the unit circle corresponding to the determinant of the arithmetic tannakian group of $M$; if the latter were finite, this would be a finite group of roots of unity. By contraposition, the result follows.

\[\Box\]

**Remark 10.12.** If $\det(M)$ is known to be generically unramified, then it suffices to assume that the tannakian determinant of $p_{1,*}M$ on $G_m$ is geometrically of infinite order, since in this case we can apply Proposition 3.43 to some twist $M(\langle \chi_1, a_1 \rangle)$ such that the set of characters $\chi$ for which the character $\langle \chi_1, a_1 \rangle \langle \chi, 0 \rangle$ is unramified is generic.

**Example 10.13.** Proposition 10.11 applies for instance to objects of the form

\[M = \mathcal{L}_n(f)(1/2)[1]\]

where $\eta$ is a non-trivial multiplicative character of $k$, and $f \in k[X]$ is a polynomial such that $f(0) \neq 0$ with degree $d \geq 2$ such that $\eta^d$ is non-trivial, as explained by Katz in [68, Th. 17.5]. Indeed, in this case, the assumption of the proposition holds for all $a \neq 0$.

The dimension formula (10.2) shows that the tannakian dimension is $d + 1$. Note that [68, Th. 17.5] provides the equidistribution for the subfamily with $a = 0$, under the assumption that $f$ is not of the form $g(X^b)$ for some $b \geq 2$, but as traces of matrices in $U_d(C)$, because the corresponding object on $G_m$ has tannakian dimension $d$. This means that the characters $\langle \chi, 0 \rangle$ are examples of weakly-unramified characters for $M$ which are not unramified (since they do not give the “right” dimension).

As explained in Remark 4.20, (2), we expect that we can apply Theorem 4.19 unconditionally to $G$. Thus this proposition should imply the following result:

**Corollary 10.14.** Let $\ell$ be a prime number. For all $p \neq \ell$, let $M_p$ be a geometrically simple perverse sheaf of weight zero on $(G_m \times G_a)_{\mathbb{F}_p}$ supported on the diagonal with $c_u(M_p) \ll 1$, where $u$ is the natural locally-closed immersion $G_m \times G_a \hookrightarrow \mathbb{A}^2 \hookrightarrow \mathbb{P}^2$. Suppose that the tannakian dimension $r$ of $M_p$ is independent of $p$ and that $M_p$ satisfies the assumption of Proposition 10.11 for $k = \mathbb{F}_p$. Then the sums

\[S(\chi, a; p) = \sum_{x \in \mathbb{F}_p^\times} t_{M_p}(x) \chi(x) e\left(\frac{ax}{p}\right)\]

for $\chi$ a multiplicative character of $\mathbb{F}_p$ and $a \in \mathbb{F}_p$ become equidistributed according to the trace of a random unitary matrix in $U_r(C)$.

**10.3. Diagonal objects of dimension 2**

The computation of Lemma 10.6 allow us, for instance, to classify those sheaves $\mathcal{M}$ which give rise to geometrically simple perverse sheaves on the diagonal with tannakian dimension $r = 2$. Indeed, the (usual) rank of $\mathcal{M}$ must be either 1 or 2.

In the first case, one and only one of the following conditions must be true:

1. $\mathcal{M}$ is lisse on $G_m$, tamely ramified at 0 and has (unique) break at $\infty$ equal to 2; if the characteristic of $k$ is not equal to 2, then the only such sheaves are isomorphic to

\[\mathcal{L}_{\psi(ax^2+bx)} \otimes \mathcal{L}_\eta\]
where \( a \neq 0 \) and \( \eta \) is a multiplicative character. The corresponding exponential sums are “twisted quadratic Gauss sums”.

(2) \( \mathcal{M} \) is lisse on \( G_m \) and has swan conductor 1 at 0 and unique break \( \leq 1 \) at \( \infty \); the only such sheaves are isomorphic to
\[
\mathcal{L}_{\psi(a/x + bx)} \otimes \mathcal{L}_\eta
\]
where \( a \neq 0 \) and \( \eta \) is a multiplicative character (we recover the example of Kloosterman–Salié sums).

(3) there exists a unique \( b \in \bar{k}^\times \) such that \( \mathcal{M} \) is lisse on \( A^1 - \{b\} \), it has unique break \( \leq 1 \) at \( \infty \) and is tamely ramified at 0 and \( b \); the only such sheaves are isomorphic to
\[
\mathcal{L}_{\eta(x-b)} \otimes \mathcal{L}_{\xi(x)} \otimes \mathcal{L}_{\psi(ax)}
\]
where \( b \neq 0 \) and \( \eta \) and \( \xi \) are multiplicative characters. These are some kinds of twisted Jacobi sums.

On the other hand, if \( \mathcal{M} \) has rank 2, then it must be lisse on \( G_m \), tamely ramified at 0 and have breaks \( \leq 1 \) at \( \infty \). Up to twist by a multiplicative character, we obtain a sheaf lisse on \( A^1 \) with breaks \( \leq 1 \) at \( \infty \). Since we assume \( \mathcal{M} \) to be geometrically irreducible, the two breaks must be equal, say equal to \( \lambda \). Their sum is the Swan conductor at \( \infty \), which is also the Euler–Poincaré characteristic (since \( \mathcal{M} \) is lisse on \( G_m \) and tame at 0, see (C.12)); thus either \( \lambda = 1/2 \) or \( \lambda = 1 \). The first case gives Euler–Poincaré characteristic equal to 1, so we have a hypergeometric sheaf of rank 2 by Katz’s classification (see Theorem B.4, e.g., a Kloosterman sheaf of rank 2 (the corresponding sums are described in Example 10.10, (2)). In the second case, we may have a pullback of such a sheaf by \( x \mapsto x^2 \). For the pullback of the Kloosterman sheaf, the exponential sums are then given by the formulas
\[
S_n(\chi, a) = \frac{1}{|k|} \sum_{x \in k^\times} \left( \sum_{y \in k^\times} \psi_n(xy + xy^{-1}) \right) \chi(x) \psi_n(ax)
\]
\[
= \frac{1}{|k|} \sum_{y \in k^\times} \sum_{x \in k^\times} \chi(x) \psi_n(x(a + y + y^{-1}))
\]
\[
= \frac{\tau(\chi, \psi_n)}{|k|} \sum_{y \in k^\times} \chi(a + y + y^{-1}),
\]
for \( \chi \) non-trivial, where \( \tau(\chi, \psi_n) \) is again the Gauss sum.

## 10.4. Negligible objects and objects of dimension one

We conclude our discussion of the group \( G = G_m \times G_a \) by classifying the negligible objects as well as the objects of tannakian dimension 1. This may be helpful for further investigations (e.g., to compute the determinant of the tannakian group in some cases, or to apply the Goursat–Kolchin–Ribet criterion, see [62, Prop. 1.8.2]).

**Proposition 10.15.** Let \( M \) be a simple perverse sheaf on \( G \) over \( \bar{k} \).

The perverse sheaf \( M \) is negligible if and only if \( M \) is isomorphic to an object of the form
\[
p_1^*(N) \otimes \mathcal{L}_{\psi(ax)}[1]
\]
for some perverse sheaf \( N \) on \( G_m \) and some \( a \), or to an object of the form
\[
\mathcal{L}_\chi[1] \otimes p_2^*(M),
\]
for some monic polynomial \( \chi(x) \in \bar{k}[x] \).

139
for some perverse sheaf $M$ on $G_a$ and some multiplicative character $\chi$.

**Proof.** It is elementary that the objects of the two forms in the statement are negligible (see Example 3.5), so we need to prove the converse.

Let $M$ be a simple negligible perverse sheaf on $G$. We fix a non-trivial additive character $\psi$ and consider the (shifted) Fourier transform $F = FT^{\psi/\chi}_{G_m}(M)[1]$ of $M$ relative to $G_m$; this is a perverse sheaf on $G$. For $a \in G_a$, the restriction $F_a$ of this complex to $G_m \times \{a\}$ is isomorphic to $p_1^!(M_{\psi(ay)})$. Hence, for a generic, the object $F_a = F|_{G_m \times \{a\}}$ is a perverse sheaf of generic rank zero by the relative generic vanishing theorem (Theorem 2.11).

We now distinguish cases according to the dimension $d$ of the support of $F$.

1. If $d = 0$, then $F$ is supported on finitely many points. Since $M$ is simple and the Fourier transform preserves simple perverse sheaves, $F$ is also simple. This implies that the support of $F$ is irreducible, and hence it is a single point $(x,a)$. The point $a$ correspond to the character $\psi(ay)$ via inverse Fourier transform. Hence, $M$ is of the form $p_1^*(N) \otimes L_{\psi(ay)}$, where $N$ is a sheaf with finite support in $G_m$, which is an object of the form (10.4).

2. If $d = 1$, then the support of $F$ is a curve $C \subset G_m \times G_a$. If, for generic $a \in G_a$, the intersection of $C$ with $G_m \times \{a\}$ is non-empty, then the support of $F_a$ is finite and non-empty, contradicting the fact that this sheaf is of generic rank zero. Hence, for generic $a \in G_a$, the intersection of $C$ with $G_m \times \{a\}$ is empty. We then deduce that $F_a = 0$ for generic $a$. Hence, $C$ is a finite union of horizontal lines. As in (1), $C$ is irreducible, and hence is of the form $G_m \times \{a\}$ for some $a \in G_a$. Hence, $M$ is of the form $p_1^*(N) \otimes L_{\psi(ay)}$ for some perverse sheaf $N$ on $G_m$; this is again of the form (10.4).

3. Finally, assume that $d = 2$. Let $\eta$ be the generic point of $G_a$. Then $F_\eta$ is a perverse sheaf with Euler–Poincaré characteristic zero on $G_m$ over $k(\eta)$. By Proposition B.3, it follows that $F_\eta$, viewed as a perverse sheaf on $G_m$ over $k(\eta)$, is geometrically isomorphic to a Kummer perverse sheaf $L_{\chi}[1]$ for some multiplicative character $\chi$. Hence, $F$ is of the form $p_2^*(N') \otimes L_{\chi}[1]$ for some perverse sheaf $N'$ on $G_a$. Taking the relative inverse (shifted) Fourier transform, we find that there exists some object $N$ of $D^b(G_a)$ such that $M$ is isomorphic to $p_2^*(N) \otimes L_{\chi}[1]$. □

We will now classify the objects of tannakian dimension one.

The most obvious objects of tannakian dimension one on $G_m \times G_a$ are those of the form $p_1^!(H) \ast \text{int} \, p_2^!(N)$, for some hypergeometric sheaf $H$ and some simple perverse sheaf $N$ on $G_a$ with Fourier transform of rank one (see Section B.4 for reminders concerning hypergeometric sheaves). The next lemma provides a third class of such objects.

**Lemma 10.16.** Let $f \in k(x)^\times$ be a rational function and $U$ a dense open set of $G_a$ where $f$ is defined and non-zero. Let $C \subset V = G_m \times U$, with coordinates $(x,a)$, be the curve with equation $f(a) = x$. Let $\overline{Q}_{t,f}$ be the intermediate extension to $G_m \times G_a$ of the constant sheaf on $C$ shifted by 1. Then the inverse relative Fourier transform $M_f$ of $\overline{Q}_{t,f}$ is a perverse sheaf on $G$ with tannakian dimension one.

**Proof.** We need to show that for generic $(\chi,b) \in \hat{G}$, we have

$$\dim H^0(G, (M_f)_{(\chi,b)}) = 1.$$ 

This cohomology group can be computed by first taking the Fourier transform of $M_f$, restricting it to the line $G_m \times \{b\}$, tensoring by $L_{\chi}$, then taking the cohomology on $G_m \times \{b\}$. Since the Fourier transform $F$ of $M_f$ is $\overline{Q}_{t,f}$, there exists a dense open set $U$ of $G_a$ such that for $b \in U$, the
restriction of \( F \) is a rank one skyscraper sheaf supported on \( f(b) \). Such a sheaf, tensored with any character \( \mathcal{L}_\chi \), has its 0-th cohomology group of dimension 1.

These three basic classes of objects of tannakian dimension 1 turn out to be sufficient to obtain all of them.

**Proposition 10.17.** Let \( M \) be a simple perverse sheaf on \( G \) over \( \overline{k} \). Then \( M \) has tannakian dimension one if and only if there exist a rational function \( f \), a hypergeometric sheaf \( H \) on \( G_m \) and a perverse sheaf \( N \) on \( G_a \) with Fourier transform of rank one such that \( M \) is isomorphic to the convolution

\[
M_f \ast \text{int} p_1^*(H) \ast \text{int} p_2^*(N).
\]

**Proof.** Since the tannakian dimension is multiplicative in convolutions, the “if” assertion follows from Lemma 10.16.

Conversely, let \( M \) be a simple perverse sheaf on \( G \) of tannakian dimension one. As in the dimension zero case, we consider the shifted Fourier transform \( F = \text{FT}_{\psi/G_m}(M)[1] \) of \( M \) relative to \( G_m \). For generic \( a \in G_a \), the object \( F_a = F|_{G_m \times \{ a \}} \) on \( G_m \times \{ a \} \) is perverse of generic rank one.

In particular, for the generic point \( \eta \) of \( G_a \), the object \( F \) viewed as a perverse sheaf on \( G_m, k(\eta) \), is of tannakian dimension one. By Theorem B.4, (2), it is isomorphic to a hypergeometric sheaf multiplicatively translated by a rational function \( f(\eta) \) of \( \eta \), and tensored by a rank one object on \( k(\eta) \). Thus, there exists a dense open subset \( U \) of \( G \) such that \( F|_U \) is of the form \( p_1^*(H)[1] \otimes m_f^*H \) where \( N \) is a perverse sheaf on \( G_a \) of generic rank one, \( H \) is a hypergeometric sheaf on \( G_m \) and \( m_f : U \to G_m \) is the morphism

\[
(x, a) \mapsto xf(a).
\]

Let \( C \) be the curve with equation \( f(a) = x \) in \( G \). The complex \( m_f^*H \) is isomorphic to the multiplicative convolution of \( p_1^*(H)[1] \) and of the intermediate extension \( \Omega_{t,f} \) to \( G \) of the constant sheaf on \( C \) (as in Lemma 10.16).

The inverse Fourier transform \( M_f \) of the intermediate extension of \( \Omega_{t,f} \) to \( G \) does not depend on the choice of \( U \) by the properties of the intermediate extension (Proposition A.9)). Since the Fourier transform sends tensors products to additive convolution, we find that \( M \) is the internal convolution of the perverse sheaves \( M_f, p_1^*(H)[1] \) and \( p_2^*(N)[1] \), where \( N \in \text{Perv}(G_a) \) is a perverse sheaf with Fourier transform of rank one.

**Remark 10.18.** The trace functions (over \( k \)) of simple negligible objects are of the form

\[
(x, y) \mapsto t(x)\psi(by)
\]

for some trace function \( t \) on \( G_m \) and some \( b \in k \), or

\[
(x, y) \mapsto \chi(x)t(y)
\]

for some trace function \( t \) on \( G_a \) and some multiplicative character \( \chi \).

The trace functions of simple objects of tannakian dimension one are multiplicative convolutions of functions of the three types

\[
(x, y) \mapsto \sum_{z \in k} \psi(-yz), \quad (x, y) \mapsto \mathcal{H}(x), \quad (x, y) \mapsto t(y),
\]

where \( f \) is a non-zero rational function, \( \mathcal{H} \) is the trace function of a hypergeometric sheaf and \( t \) is the trace function of an object on \( G_a \) whose Fourier transform has generic rank one. The associated
exponential sums are (up to normalization by powers of $|k|$) of the form

$$S(\chi, a) = \chi(f(a))\hat{H}(\chi)\hat{t}(a),$$

where $\hat{t}$ is the trace function of an $\ell$-adic character, and $\hat{H}$ is a product of monomials in Gauss sums (see (B.1)).

To check this, it is enough to compute the trace function of the objects of Lemma 10.16. We use the notation there. The trace function of $Q_{\ell,f}$ at $(x, a) \in G(k)$ is equal to 1 if $f(a) = x$, and 0 otherwise. So the trace function of $M_f$ takes value

$$\sum_{y \in k \atop f(y) = x} \psi(-ay)$$

at $(x, a)$. For $(\chi, b) \in \hat{G}(k)$, we get the Mellin transform

\[
\sum_{(x, a) \in G(k)} \chi(x)\psi(ba) \sum_{y \in k \atop f(y) = x} \psi(-ay) = \sum_{y \in k} \sum_{a \in k} \chi(f(y))\psi(a(b - y)) = |k|\chi(f(b)).
\]
CHAPTER 11

Variance of arithmetic functions in arithmetic progressions

11.1. Introduction

In this chapter, we will consider some of the first natural concrete applications of our results to problems which, as stated, do not seem to refer to algebraic groups, or equidistribution statements of any kind. These problems are related to one of the most essential questions of modern analytic number theory, namely the study of arithmetic functions in arithmetic progressions to large moduli.

Concretely, this means that we are given an arithmetic function $f$ (i.e., a complex-valued function defined on the set of positive integers), an integer $q \geq 1$ (the “modulus”) and $x \geq 2$, and we seek to understand the quantities

$$\sum_{\substack{n \leq x \atop n \equiv a \pmod{q}}} f(n)$$

for $a$ varying among residue classes modulo $q$, or only for $a$ coprime to $q$. The focus is on these sums in settings where both $x$ and $q$ are large, and the goal is often to obtain asymptotic formulas valid for $q$ as large as possible in comparison with $x$.

The literature on this topic is enormous, and the applications cover almost all of analytic number theory: indeed, this subject encompasses, almost by definition, all of sieve theory and its applications (see [42]), and it is in particular at the source of most of the recent developments in prime number theory, going back to the Bombieri–Vinogradov Theorem (see, e.g., [59, Ch. 17]), and including such celebrated results as the Green–Tao Theorem, or Zhang’s Theorem [114], or the Maynard–Tao method (see, e.g., [78]).

The problems that we consider here are the analogue for polynomials over finite fields, and in the limit when the size of the field tends to infinity, of questions related to the distribution of the quantities above, and especially of the variance as a function of $a$. In other words, we are interested in

$$\sum_{a \pmod{q}} \left| \sum_{n \leq x \atop n \equiv a \pmod{q}} f(n) - \frac{1}{q} \sum_{n \leq x} f(n) \right|^2$$

or (often more naturally for applications) the variant

(11.1) $$\sum_{\substack{a \pmod{q} \atop (a, q) = 1}} \left| \sum_{n \leq x \atop n \equiv a \pmod{q}} f(n) - \frac{1}{\varphi(q)} \sum_{n \leq x} f(n) \right|^2$$

where the sum covers only invertible residue classes. (In both cases, the choice of “expected main term” is natural, but might require adjustments, depending on the arithmetic function involved.)

The serious study of these function field analogues has been initiated especially by Keating and Rudnick and a number of collaborators (see for instance [74], in the case where $f$ is the von Mangoldt function, using results of Katz [69], which themselves relied on his work on the Mellin transform over finite fields [68]).
It is quite easy to understand the link between a quantity like (11.1), in the function field case, and equidistribution problems of the type considered in Chapter 4. Indeed, we are then in the situation where \( q \) is a polynomial in \( k[t] \) for some finite field \( k \), and the sum over \( n \leq x \) is replaced by the sum over monic polynomials \( g \in k[t] \) of degree \( m \). Then for any complex-valued function \( f \) defined for polynomials in \( k[t] \), we see (using orthogonality of characters, or the discrete Plancherel formula) that the formula

\[
\sum_{a \in (k[t]/qk[t])^\times} \left| \sum_{g \equiv a \pmod{q}} f(g) \right|^2 = \sum_{g \in (k[t]/qk[t])^\times} f(g) \quad (11.1)
\]

holds, where \( \chi \) runs over non-trivial characters of the group \((k[t]/qk[t])^\times\). These characters can be identified with the characters of \( G(k) \) for some commutative algebraic group \( G \) (by a simple special case of geometric class-field theory; in the case which we will consider, when \( q \) is squarefree, it will be a very explicit torus). Moreover, for many natural arithmetic functions, the inner sum over \( g \) monic of degree \( m \) in \( k[t] \) can be interpreted as the value at \( \chi \) of the arithmetic Fourier transform of some object on this group \( G \). In the limit where \( k \) is replaced by its extensions \( k_n \) of degree \( n \to +\infty \) (and \( m \) is fixed), we can therefore expect to determine the asymptotic behavior of this variance from our equidistribution theorems.

We will now consider in detail the version of this question when \( f \) is the von Mangoldt function associated to a higher-degree \( L \)-function (the classical von Mangoldt function being related to the Riemann zeta function, which has degree 1), in which case Hall, Keating, and Roddity-Gershon [52] have shown that new phenomena appear (again relying on [68]). These are conjectured to correspond to new behavior also in the (currently inaccessible) situation over number fields. We refer the reader to the introductions of both papers [74] and [52] for extensive discussions of these motivating conjectures, and for additional references to other papers.

We will see that, as suggested by the discussion above, the equidistribution theory for arithmetic Fourier transforms on higher-dimensional tori leads to generalizations, strengthenings, and better understanding, of these previous results. This leads in particular to Theorem 3 in the Introduction, but the method is suitable for the proof of many similar statements.

In the remainder of this chapter, as before, we denote by \( k \) a finite field, with an algebraic closure \( \bar{k} \), and for each \( n \geq 1 \) by \( k_n \) the extension of degree \( n \) of \( k \) in \( \bar{k} \). We fix a prime \( \ell \) distinct from the characteristic of \( k \), and all complexes are understood to be \( \ell \)-adic complexes.

### 11.2. Equidistribution on tori associated to polynomials

In what follows, we fix a square-free monic polynomial \( f \in k[t] \) of degree \( d \geq 2 \). We denote by \( B \) the (étale) \( k \)-algebra \( B = k[t]/fk[t] \) of degree \( d \) over \( k \) (in spite of the notation, \( B \) depends on \( f \)), by \( Z \) the zero locus of \( f \), and by \( \mathbb{A}^1_k[1/f] \) the complement of \( Z \) in the affine line over \( k \).

We begin with a result of Katz [69].

**Proposition 11.1** (Katz). The functor \( A \mapsto (B \otimes_k A)^\times \) on \( k \)-algebras is represented by a torus \( T \) defined over \( k \). This torus splits over any extension of \( k \) where \( f \) splits in linear factors.

Moreover, the map \( x \mapsto t - x \) defines a closed immersion

\[
i_f : \mathbb{A}^1_k[1/f] \longrightarrow T,
\]
and there exists a morphism of algebraic groups
\[ p : T \to G_m \]
satisfying \( p \circ i_f = (-1)^{\deg(f)} f \), where we view \( f \) as defining a morphism \( A^1[1/f] \to G_m \).

**Remark 11.2.** As noted by Katz [69, p.3224], the torus \( T \) is isomorphic to a generalized jacobian associated to \( \mathbb{P}^1 \) with divisor \((\infty) + Z\) (compare Remark 9.13).

We call the morphism \( p \) the norm. If \( f \) splits completely over \( k \), say
\[ f = \prod_{z \in \mathbb{Z}} (t - z), \]
then the torus \( T \) is split by the morphism sending \( g \) to \((g(z))_{z \in \mathbb{Z}}\). The norm is then given by
\[ p(g) = \prod_{z \in \mathbb{Z}} g(z), \]
and in particular one has
\[ p(i_f(x)) = \prod_{z \in \mathbb{Z}} (z - x) = (-1)^{\deg(f)} f(x). \]

We denote by \( \hat{B}^\times \) (resp. by \( \hat{k}^\times \)) the group of \( \ell \)-adic characters of the finite group \( B^\times \) (resp. of \( k^\times \)). We extend characters of \( B^\times \) to \( k[l] \) by putting \( \chi(g) = 0 \) if \( g \) is not coprime to \( f \). Since \( B^\times = T(k) \), the group \( \hat{B}^\times \) of characters of \( B^\times \) is also equal to the group \( \hat{T}(k) \) of characters of \( T(k) \) (although we will sometimes distinguish them to avoid confusion between characters of \( B \), operating on polynomials, and characters of \( T \)).

If \( f \) splits over \( k \) as above, then the Chinese Remainder Theorem induces an isomorphism \((\hat{k}^\times)^Z \to \hat{B}^\times \), under which an element \((\chi_z)_{z \in \mathbb{Z}} \in (\hat{k}^\times)^Z\) corresponds to the character \( \chi \) of \( B^\times \) that maps \( g \in k[l] \) to
\[ \chi(g) = \prod_{z \in \mathbb{Z}} \chi_z(g(z)). \]

Let \( M \) be a perverse sheaf on \( A_k^1[1/f] \) which is pure of weight zero. We are interested in the distribution properties of families of one-variable exponential sums of the type
\[ (11.2) \quad \sum_{x \in k - \mathbb{Z}} t_M(x) \chi(t - x) \]
for \( \chi \in \hat{B}^\times \), or of the underlying \( L \)-functions (recall that \( t \) is an indeterminate).

We start by interpreting these sums as Mellin transforms on \( T \) in order to apply our general equidistribution results. Let \( \chi \in \hat{B}^\times \). Let \( \tilde{\chi} \) be the character of \( T(k) \) corresponding to \( \chi \). The sum \((11.2)\) takes the form
\[ (11.3) \quad \sum_{x \in k} t_M(x) \chi(t - x) = \sum_{x \in A^1[1/f](k)} t_M(x) \tilde{\chi}(i_f(x)) = \sum_{y \in T(k)} t_{i_f \ast M}(y) \tilde{\chi}(y). \]

Note also that by adapting the argument of [69, Lem.1.1], for any \( n \geq 1 \), we have
\[ (11.4) \quad \sum_{x \in k_n} t_M(x; k_n) \chi(N_{k_n/k}(t - x)) = \sum_{y \in T(k_n)} t_{i_f \ast M}(y; k_n) \tilde{\chi}(N_{k_n/k}(y)). \]

The variation with \( \chi \in \hat{B}^\times \) of the sums \((11.2)\) is therefore governed by the tannakian group of the perverse sheaf \( i_f \ast M \) on \( T \). By Theorem 3.25, this perverse sheaf is generically unramified.

We first compute the tannakian dimension of the object \( i_f \ast M \), in the most important cases.
Lemma 11.3. Let \( \mathcal{F} \) be a middle extension sheaf on \( \mathbf{A}^1_k[1/f] \) which is pure of weight zero. Define \( M = \mathcal{F}(1/2)[1] \), which is a perverse sheaf of weight zero on \( T \). The tannakian dimension \( r \) of \( i_f^*M \) is given by

\[
r = (\deg(f) - 1) \text{rank}(\mathcal{F}) + \sum_{x \in \mathbf{P}^1(k)} \text{swan}_x(\mathcal{F}) + \sum_{x \in k} \text{drop}_x(\mathcal{F}) \geq (\deg(f) - 1) \text{rank}(\mathcal{F}).
\]

Proof. The object \( M \) is a perverse sheaf and so is \( i_f^*M \) because \( i_f \) is a closed immersion (see Corollary A.8). The tannakian dimension is the Euler–Poincaré characteristic \( \chi_c(T_k, (i_f^*M)_x) \) for a generic character \( \chi \in \hat{T} \) (Proposition 3.16).

For any integer \( i \), we have natural isomorphisms

\[
H^i_c(T_k, (i_f^*M)_x) \simeq H^i_c(\mathbf{A}^1[1/f]_k, M \otimes i_f^*\mathcal{L}_\chi) \simeq H^i_c(\mathbf{A}^1[1/f]_k, \mathcal{F}[1] \otimes i_f^*\mathcal{L}_\chi)
\]

As explained in [69, p. 3227], the pullback \( i_f^*\mathcal{L}_\chi \) is geometrically isomorphic to the tensor product

\[
\mathcal{L} = \bigotimes_{z \in \mathbb{Z}} \mathcal{L}_{\chi(z-x)}
\]

where \( x \) is the coordinate on \( \mathbf{A}^1[1/f] \) and \( \chi \) corresponds to the tuple \( (\chi_z) \) of characters of \( k^\times \) as above.

Now using the Euler–Poincaré formula on a curve (see Theorem C.2), we obtain

\[
r = -\chi_c(\mathbf{A}^1[1/f]_k, \mathcal{F} \otimes \mathcal{L}) = -\text{rank}(\mathcal{F})\chi_c(\mathbf{A}^1[1/f]_k)
+ \sum_{x \in \mathbf{P}^1} \text{swan}_x(\mathcal{F} \otimes \mathcal{L}) + \sum_{x \in \mathbf{A}^1[1/f]} \text{drop}_x(\mathcal{F} \otimes \mathcal{L})
\]

where \( \text{swan}_x \) and \( \text{drop}_x \) are the Swan conductors and the drop at \( x \), respectively.

The first term is equal to \( \text{rank}(f)(\deg(f) - 1) \) since \( f \) is square-free, and the second is the sum of Swan conductors of \( \mathcal{F} \), since the sheaf \( \mathcal{L} \) is everywhere tame. The third is the sum of the drops of \( \mathcal{F} \) on \( \mathbf{A}^1[1/f] \), since \( \mathcal{L} \) is lisse on \( \mathbf{A}^1[1/f] \). \( \square \)

We now apply Larsen’s alternative to compute the tannakian group of such perverse sheaves.

Proposition 11.4. Let \( \mathcal{F} \) be a middle extension sheaf on \( \mathbf{A}^1_k[1/f] \) which is pure of weight zero and irreducible of rank at least 2. Let \( M = \mathcal{F}(1/2)[1] \). Assume that \( M \) is not geometrically isomorphic to \( i_f^*\mathcal{L}_\chi[1] \) for some character \( \chi \) of \( G \).

Then \( i_f^*M \) is a geometrically simple perverse sheaf, pure of weight zero and of tannakian dimension at least 2.

Moreover, if \( \deg(f) \geq 2 \), then the fourth moment of the tannakian group \( G_{i_f,M}^{w_2} \) of \( i_f^*M \) is equal to 2, and if \( \deg(f) \geq 4 \), then the eighth moment is equal to 24.

Proof. The previous lemma implies that \( i_f^*M \) has tannakian dimension \( \geq 2 \). It is geometrically simple since \( M \) is.

One argument to obtain the result is to observe that \( i_f \) is a Sidon morphism when \( \deg(f) \geq 2 \), and a 4-Sidon morphism when \( \deg(f) \geq 4 \) (by Proposition 9.10, (4), since these properties can be checked after a finite extension), so that the result follows from Proposition 9.7 since the tannakian dimension is \( \geq 2 \), and the assumption on \( M \).

For the sake of concreteness, we show also how to perform the computation of the eighth moment using the interpretation of the sums in terms of Dirichlet characters. The eighth moment
of the full family of exponential sums over \( k \) is equal to
\[
\frac{1}{|B^\times|} \sum_{\chi \in B^\times} \left| \sum_{x \in k} t_M(x) \chi(t - x) \right|^8 = \sum_{x_1, \ldots, x_8} \prod_{i=1}^4 t_M(x_i) \prod_{i=5}^8 t_M(x_i) \times \frac{1}{|B^\times|} \sum_{\chi \in B^\times} \chi((t - x_1) \cdots (t - x_8)) \chi((t - x_5) \cdots (t - x_8)).
\]

By orthogonality, the inner sum is 0 unless
\[
(t - x_1) \cdots (t - x_4) \equiv (t - x_5) \cdots (t - x_8) \pmod{f},
\]
in which case it is equal to 1. Since the degree of \( f \) is at least 4, this can only happen when
\[
(t - x_1) \cdots (t - x_4) = (t - x_5) \cdots (t - x_8)
\]
in \( k[t] \). We then distinguish according to the size of \( \{x_1, \ldots, x_4\} \). If this set has four elements, then so does \( \{x_5, \ldots, x_8\} \), and the two sets are equal. The contribution arising from this case is
\[
\sum_{x_1, \ldots, x_4} \sum_{\sigma \in S_4} t_M(x_1) \cdots t_M(x_4) \overline{t_M(x_{\sigma(1)})} \cdots \overline{t_M(x_{\sigma(4)})} = 24 \left( \sum_{x \in k} |t_M(x)|^2 \right)^4.
\]

On the other hand, if \( \{x_1, \ldots, x_4\} \) has three elements, say \( x, y, \) and \( z \), then so does \( \{x_5, x_6, x_7, x_8\} \), and there are an absolutely bounded number of possibilities for \( (x_1, x_2, x_3, x_4) \) given \( x, y \) and \( z \). A similar result holds for two or one elements, and since \( t_M(x) \ll |k|^{-1/2} \), one sees that these altogether contribute at most
\[
\frac{1}{|k|^4} \sum_{x, y, z \in k} 1 \ll \frac{1}{|k|}.
\]

These computations can be repeated over \( k_n \) for \( n \geq 1 \) using (11.4), and using Proposition 9.1, we deduce by letting \( n \to +\infty \) that
\[
\frac{1}{|B^\times|} \sum_{\chi \in B^\times} \left| \sum_{x \in k} t_M(x) \chi(t - x) \right|^8 \to 24
\]
as \( |k| \to +\infty \).

Finally, the usual argument using the definition of generic sets of characters together with (11.3) and the Riemann Hypothesis imply that
\[
\frac{1}{|B^\times|} \sum_{\chi \in B^\times} \left| \sum_{x \in k} t_M(x) \chi(t - x) \right|^8 \to 0,
\]
so that Proposition 9.3 gives the result. \( \square \)

**Corollary 11.5.** Under the assumptions of the proposition, the tannakian group of \( i_{f,*} M \) contains \( SL_r \), where \( r \) is the tannakian dimension of \( i_{f,*} M \), if \( \deg(f) \geq 4 \).

**Proof.** By Lemma 11.3, the assumption implies \( r \geq 4 \), and the result follows from Larsen’s Alternative, in the form of the eighth moment theorem of Guralnick and Thiep (see Theorem 9.4 (4)). \( \square \)
11.3. Application to von Mangoldt functions

Suppose again that $M$ is of the form $F(1/2)[1]$ for some middle extension sheaf $F$ on $A^1_k[1/f]$ which is pure of weight zero and geometrically irreducible of rank at least 2.

The statement of equidistribution on average for the object $i_{f^*}M$ leads automatically to distribution statements of any “continuous” function of the polynomials in the variable $T$ which are the twisted $L$-functions of $M$, namely

$$
\det(1 - \text{Fr}_k T \mid H^0_c(A^1[1/f]_k, M \otimes L_{\chi})) = \det(1 - \text{Fr}_k T \mid H^0_c(T_{\bar{k}}, (i_{f^*}M)_\chi))
$$

as $\chi \in \bar{B}^\times$ varies, where $\bar{\chi}$ is now the character of the fundamental group of $A^1_k[1/f]$ that corresponds to $\chi$ by class-field theory, and $L_{\bar{\chi}}$ is the associated rank one sheaf. (Note that, for this purpose, Theorem 4.4 is sufficient.)

For instance, this leads to statements concerning the variance of von Mangoldt functions in arithmetic progressions, as we now explain.

Write

$$
L(M, T) = \det(1 - \text{Fr}_k T \mid H^0_c(A^1[1/f]_k, M)) = \prod_x \det(1 - \text{Fr}_{k_{\deg(x)}} T^{\deg(x)} \mid F_x)^{-1},
$$

where $x$ runs over the set of closed points of $A^1_k[1/f]$, which may be identified with the set of irreducible monic polynomials in $k[t]$ which are coprime to $f$. Expanding the logarithmic derivative of the local factor at a closed point $x$, corresponding to an irreducible monic polynomial $\pi \in k[t]$, we have

$$
-Td \log(\det(1 - \text{Fr}_x T^{\deg(x)} \mid F_x)^{-1}) = \sum_{\nu \geq 1} \Lambda_{M}(\pi^{\nu})T^{\nu \deg(\pi)},
$$

which defines the von Mangoldt function $\Lambda_{M}(\pi^{\nu})$ for any monic irreducible polynomial $\pi$ coprime to $f$ and any $\nu \geq 1$. We further define $\Lambda_{M}(g) = 0$ if $g \in k[t]$ is not a power of such an irreducible polynomial. The full logarithmic derivative then has the formal power series expansion

$$
-TL'(M, T) = \sum_g \Lambda_{M}(g)T^{\deg(g)}
$$

over all monic polynomials $g \in k[t]$.

For an integer $m \geq 1$ and a polynomial $a \in k[t]$, we then define

$$
\psi_M(m; f, a) = \sum_{\deg(g) = m, g \equiv a \pmod{f}} \Lambda_{M}(g).
$$

We consider the average

$$
A_M(m; f) = \frac{1}{|B^\times|} \sum_{a \in B^\times} \psi_M(m; f, a)
$$

and the variance

$$
V_M(m; f) = \frac{1}{|B^\times|} \sum_{a \in B^\times} |\psi_M(m; f, a) - A_M(m; f)|^2.
$$

These are related to exponential sums as follows.
Proposition 11.6. With assumptions and notation as above, we have

\[ V_M(m; f) = \frac{1}{|B^\times|^2} \sum_{\chi \in B^\times, \chi \neq 1} V_M(m; \chi) \]

where

\[ V_M(m; \chi) = \left| \sum_{x \in k_m} t_M(x; k_m) \chi(N_{k_m/k}(t - x)) \right|^2. \]

In particular, if \( \chi \) is weakly unramified for \( i_f \star M \), then we have \( V_M(m; \chi) = |\text{Tr}(\Theta_M(\chi^m))|^2 \).

Proof. The first part is proved, using the orthogonality of characters, exactly like [52, §6, (6.3.4)]. The second assertion then follows from Lemma 3.33 and (11.4).

Remark 11.7. The von Mangoldt function can be replaced by many other arithmetic functions in this argument; we refer to the discussion by Sawin in [101] (which proves analogue equidistribution statements to ours for the case of “short intervals”, which amounts to considering a unipotent group instead of a torus) and to [102] for a discussion of how classical arithmetic functions which are related to “factorization functions” (functions of polynomials \( g \) that depend only on the factorization type of \( g \)) can be interpreted as trace functions using representation theory of the symmetric groups.

We now obtain a formula for the variance, with some additional assumption.

Corollary 11.8. In addition to the assumptions of this section, assume that \( m \geq 2 \), and that the tannakian determinant of \( M \) is geometrically of infinite order. Then

\[ \lim_{|k| \to +\infty} |B^\times|^2 V_M(m; f) = \min(m, r), \]

where \( r \) is the tannakian dimension of \( i_f \star M \).

Proof. Combined with Corollary 11.5, the assumption implies that the arithmetic and geometric tannakian groups of \( i_f \star M \) are both equal to \( \text{GL}_r \). Thus the limit exists by Theorem 4.15 and is equal to

\[ \int_{U_r(\mathbb{C})} |\text{Tr}(g^m)|^2 d\mu(g) \]

where \( \mu \) is the Haar probability measure. This matrix integral is equal to \( \min(m, r) \) by work of Diaconis and Evans [31, Th. 2.1].

To check the assumption on the tannakian determinant, we have a first general criterion, which is however quite restricted.

Proposition 11.9. With notation and assumptions as above, suppose that there exists \( z \in \mathbb{Z} \) such that the local monodromy representation of \( \mathcal{F} \) at \( z \) has a non-zero unipotent tame component while the local monodromy at infinity has no unipotent tame component. Then the tannakian determinant of \( i_f \star M \) is geometrically of infinite order.

Proof. We apply Corollary 3.45 to the norm morphism \( p: T \to G_m \). Indeed, \( p \circ i_f \) coincides with the finite morphism \( \varepsilon f: \mathbb{A}^1[1/f] \to G_m \), where \( \varepsilon = (-1)^{\deg(f)} \) (Proposition 11.1), so that the equalities \( Rp_t(i_f \star M) = Rp_t(i_f \star M) = (\varepsilon f)_t \star M = ((\varepsilon f) \cdot \mathcal{F})[1](1/2) \) hold, and the sheaf
\[(\varepsilon f)_*\mathcal{F}|[1](1/2) = ((\varepsilon f)_*\mathcal{F})_0|([1](1/2)\text{ has no tame unipotent local monodromy at infinity, but has some non-trivial tame unipotent monodromy at 0 since we have a canonical isomorphism}

\[(\varepsilon f)_*\mathcal{F}_0 \simeq \bigoplus_{z \in \mathbb{Z}} \mathcal{F}_z.\]

Hence, the tannakian determinant of the object \(i_f_*\mathcal{M}\) is geometrically of infinite order. \(\Box\)

We now explain the proof of Theorem 3, where we will also use a different approach to checking that the tannakian determinant has infinite order, which may be useful in other contexts.

Let \(\pi: \mathcal{E} \to \mathbb{P}^1\) be the morphism which “is” the Legendre elliptic curve. We start with the sheaf \(\mathcal{F} = R^1\pi_*\mathbb{Q}_\ell(1/2)\).

This is a middle extension sheaf on \(\mathbb{A}^1_k\). It is pure of weight zero and geometrically irreducible of rank 2 (in particular, its \(H^2\) vanishes), and is tamely ramified at 0, 1 and \(\infty\), with drop equal to 1 at 0 and 1. Using Lemma 11.3, we compute that the tannakian dimension is \(r = 2 \deg(f) - 2 + a\), where \(a\) is the degree of the gcd of \(f\) and \(t(t-1)\).

Now the pullback of \(\mathcal{F}\) to \(\mathbb{A}^1_k[1/f]\) is a middle extension sheaf, geometrically irreducible of rank 2 and pure of weight 0, for which we keep the same notation. We can then apply Corollary 11.8 to \(\mathcal{F}\), using the following proposition. In order to conclude after doing so, we check that the contribution of the local factors at \(z \in \mathbb{Z}\) to the L-functions (which might not be of weight 0) is negligible (compare [52, Prop. 6.5.3]).

**Proposition 11.10.** Let \(M = \mathcal{F}|[1](1/2)\). The tannakian determinant of \(i_f_*\mathcal{M}\) is geometrically of infinite order.

**Proof.** If \(f\) is not coprime to \(t(t-1)\), then we can apply Proposition 11.9, since \(\mathcal{F}\) has non-trivial tame unipotent monodromy at 0 and 1, and none at infinity. So we assume that \(f\) is coprime with \(t(t-1)\).

We may assume that the polynomial \(f\) splits in linear factors over \(k\) and that \(k \neq \mathbb{Z} \cup \{0, 1\}\). Fix a non-trivial additive character \(\psi\) of \(k\). We will then prove in Proposition 11.11 below, using the theory of local constants, that there exists a generic set of characters \(\mathcal{X} \subset \mathcal{X}(M)\) and elements \(\xi_z \in \mathbb{A}^1[1/f]\) such that for \(n \geq 1\) and \(\chi \in \mathcal{X}(k_n)\), the equality

\[\det(\Theta_{M,k_n}(\chi)) = \gamma^n H_1(\chi)^{-1} H_2(\prod_{z \in \mathbb{Z}} \chi_z^{-1})^{-1}\]

holds, for some number \(\gamma\) independent of \(\chi\) and \(n\), where the functions \(H_1\) and \(H_2\) are products of Gauss sums described in (11.6) and (11.7) below.

On \(\mathbb{G}_m\), the function

\[\chi_z \mapsto \chi_z(\xi_z) \frac{1}{|k|} \left( \sum_{y \in k^n} \chi_z(y) \psi(y) \right)^2\]

coincides for \(\chi_z\) non-trivial with the arithmetic Mellin transform of the multiplicative translated hypergeometric sheaf \(\text{Hyp}_{\xi_z}(!, \psi, 1, 1; \emptyset)(1/2)\) (see (B.1) for this; in this case, this is a shifted and translated Kloosterman sheaf). Since the function \(\chi \mapsto H_1(\chi)^{-1}\) is the product of these functions over \(z \in \mathbb{Z}\), it coincides generically with the Mellin transform on \(T\) of the tensor product

\[\bigotimes_{z \in \mathbb{Z}} p^*_z \text{Hyp}_{\xi_z^{-1}}(!; \psi, 1, 1; \emptyset)(1/2),\]

150
where $p_z$ is the projection from $T$ to the $z$-component in the splitting $g \mapsto (g(z))$ of the torus $T$. (Indeed, this reflects the formula

$$\sum_{x \in T(k)} \chi(x) \prod_{z \in \mathbb{Z}} f_z(p_z(x)) = \prod_{(z_x) \in (k^{\times})^\mathbb{Z} \times \mathbb{Z}} \prod_{z \in \mathbb{Z}} \chi_z(x_z) \prod_{z \in \mathbb{Z}} f_z(x_z) = \prod_{z \in \mathbb{Z}} \sum_{x \in k^{\times}} \chi_z(x) f_z(x)$$

for arbitrary functions $f_z$ on $k^{\times}$.)

Similarly, the function $\chi \mapsto H_2(\prod \chi_z^{-1} z^{-1})$, which only depends on the product $\eta$ of the component characters $(\chi_z)$, coincides (for $\eta$ non-trivial) with the arithmetic Mellin transform of the object $\Delta_\ast L$, where $L = \text{Hyp}(!, \psi, \lambda_2, \lambda_2; \emptyset)(1/2)$ and $\Delta: G_m \to G_m^{\mathbb{Z}} \simeq T$ is the closed immersion $x \mapsto (x-1, \ldots, x-1)$. This reflects the fact that $\Delta$ is a morphism of algebraic groups, and that the dual $\hat{\Delta}$ on $\hat{T}(k)$ is given by

$$(\chi_z)_{z \in \mathbb{Z}} \mapsto \prod_{z \in \mathbb{Z}} \chi_z^{-1}.$$  

By Theorem 7.1, the formula (11.5) therefore implies that the tannakian determinant of $M$ is geometrically isomorphic in $P(T)$ to the perverse sheaf

$$D = (\Delta_\ast L) \ast \left( \bigotimes_{z \in \mathbb{Z}} p_z^* \text{Hyp}_{\xi_z}(!, \psi, 1, 1; \emptyset)(1/2) \right).$$

The object $D$ visibly has infinite geometric tannakian group since for any $m \geq 1$, we have

$$D^{\ast m} = (\Delta_\ast L)^{\ast m} \ast \left( \bigotimes_{z \in \mathbb{Z}} p_z^* \text{Hyp}_{\xi_z^{-1}}(!, \psi, 1, 1; \emptyset)^{\ast m}(1/2) \right),$$

in $P(T)$, and the $m$-th convolution powers on $G_m$ of the hypergeometric complexes that appear are not geometrically trivial (see Theorem B.4). \hfill \Box

We complete this section by proving the formula for the determinant.

**Proposition 11.11.** Suppose that $f$ splits in linear factors over $k$. For $z \in \mathbb{Z}$, define

$$\xi_z = z(z-1) \prod_{x \in \mathbb{Z}-\{z\}} (z-x)^2 \in k^{\times}.$$  

There exist numbers $\varepsilon_0, \varepsilon_1$ with the following property. For a character $\chi \in \mathcal{X}(M)$ such that all components $\chi_z$ for $z \in \mathbb{Z}$ are non-trivial, and such that the product of the components is not of order at most 2, we have

$$(11.5) \quad \det(\Theta_M(\chi))^{-1} = (-1)^r |k| \varepsilon_0 \varepsilon_1 H_1(\chi) H_2(\prod_{z \in \mathbb{Z}} \chi_z^{-1})$$

where

$$(11.6) \quad H_1(\chi) = \prod_{z \in \mathbb{Z}} \chi_z(\xi_z^{-1}) |k| \left( \sum_{y \in k^{\times}} \chi_z(y) \psi(y) \right)^{-2},$$

$$(11.7) \quad H_2(\chi) = |k| \left( \sum_{y \in k^{\times}} (\lambda_2 \chi)(y) \psi(y) \right)^{-2}.$$  

151
**Proof.** Let \( j: \mathbb{A}^1[1/f] \to \mathbb{P}^1 \) be the open immersion. Let \( \chi \in \hat{\mathbb{B}} \) be a Dirichlet character and \( \mathcal{L}_\chi \) the lisse rank 1 sheaf on \( \mathbb{A}^1[1/f] \) that corresponds to it. The \( L \)-function of \( j_!(M \otimes \mathcal{L}_\chi) \) satisfies a functional equation of the form

\[
L(j_!(M \otimes \mathcal{L}_\chi), T) = \varepsilon(\chi) T^a L(D(j_!(M \otimes \mathcal{L}_\chi)), T^{-1})
\]

where \( a = -\chi(j_!(M \otimes \mathcal{L}_\chi)) = -r \) is an integer and

\[
\varepsilon(\chi) = \det(- Fr_k | H^0(\mathbb{P}^1, j_!(M \otimes \mathcal{L}_\chi)))^{-1} = \det(- Fr_k | H^0_\varepsilon(A_k[1/f], M \otimes \mathcal{L}_\chi))^{-1}
\]

(see, e.g., [87, 3.1.1.3], [3.1.5.1]) or the reminder in Section C.1).

By Lemma 3.33, if \( \chi \in \hat{\mathbb{T}} \) is unramified for \( M \), then we deduce that

\[
\det(\Theta_M(\chi)) = (-1)^r \varepsilon(\chi)^{-1},
\]

where \( r \) is the tannakian dimension of \( i_{f*}M \). By a theorem of Laumon,\(^1\) we can express the constant \( \varepsilon(\chi) \) as a product over closed points

\[
\varepsilon(\chi) = |k|^{-2} \prod_{x \in [\mathbb{P}^1]} \varepsilon_x(\chi)
\]

of local constants, previously defined by Deligne [25] and characterized by the properties of [87, Th. 3.1.5.4]. Precisely, fixing a non-trivial additive character \( \psi \) of \( k \) and a non-zero meromorphic differential 1-form \( \omega \) on \( \mathbb{P}^1 \), we can then define

\[
\varepsilon_x(\chi) = \varepsilon(\mathbb{P}^1_x, j_!(M \otimes \mathcal{L}_\chi)|_{\mathbb{P}^1_x}, \omega|_{\mathbb{P}^1_x})
\]

with the notation of loc. cit. See again Section C.1; in particular the factor \( |k|^{-2} \) above is given by (C.1), namely the exponent is obtained by the computation

\[
-2 = 1 \cdot (1 - 0) \cdot (-2),
\]

where \( -2 \) is the generic rank of the object \( M \) (a sheaf of rank 2 in degree \(-1\)).

We take \( \omega = dt \), where \( t \) is the standard coordinate on \( \mathbb{P}^1 \). The data of \( \psi \) and \( \omega \) allows us to define non-trivial additive characters \( \psi_x \) of the completed local field at any closed point \( x \in [\mathbb{P}^1] \) by the recipe in [87, Th. 3.1.5.4, (v)]. For all closed points \( x \in \mathbb{A}^1 \), the character \( \psi_x \) is of conductor zero since \( \omega \) is regular at \( x \) (see [87, 3.1.3.6]). For \( x = \infty \), we have \( c(\psi_\infty) = -2 \) since \( \omega \) has a double pole at \( \infty \).

The main tool to compute the local constants is the formula (C.7) for twisting by a lisse sheaf: for any closed point \( x \), if \( K \) is an \( \ell \)-adic complex on the trait \( \mathbb{P}^1_x \) and \( F \) is a lisse \( \mathbb{Q}_\ell \)-sheaf on \( \mathbb{P}^1_x \) of rank \( r(F) \), then we have

\[
\varepsilon(\mathbb{P}^1_x, (K \otimes F)|_{\mathbb{P}^1_x}, \omega|_{\mathbb{P}^1_x}) = \det(Fr_x | F)^{a(\mathbb{P}^1_x, K, \omega|_{\mathbb{P}^1_x})} \varepsilon(\mathbb{P}^1_x, K, \omega|_{\mathbb{P}^1_x})^{r(F)},
\]

where the local exponent \( a(\mathbb{P}^1_x, K, \omega|_{\mathbb{P}^1_x}) \) is defined in (C.3) and (C.4). Moreover, we will often use the formula

\[
\varepsilon(\mathbb{P}^1_x, K[1], \omega) = \varepsilon(\mathbb{P}^1_x, K, \omega)^{-1}
\]

(see (C.10)).

Let \((\chi_x)_{x \in \mathbb{Z}}\) be the tuple of characters corresponding to \( \chi \). We recall that \( \mathcal{L}_\chi \) is isomorphic to \( \bigotimes_{x \in \mathbb{Z}} \mathcal{L}_{\chi_x}(-t) \).

We now compute the local constants, distinguishing between the cases \( x \in \mathbb{A}^1 \setminus \{0, 1\} \cup \mathbb{Z} \), \( x \in \{0, 1\} \), \( x \in \mathbb{Z} \) and \( x = \infty \).

\(^1\) Which, in the case we use it, goes back to Deligne [25, Th. 9.3]; see [87, 3.2.1.9] for references.
Case 1. Let $x \in A^1$ and $x \notin Z \cup \{0, 1\}$. In this case, $M \otimes \mathcal{L}_\chi$ is a lisse sheaf shifted by 1, and since $c(\psi_x) = 0$, we find
\begin{equation}
(11.10) \quad \varepsilon_x(\chi) = 1
\end{equation}
by (11.9).

Case 2. Let $x \in \{0, 1\}$. Then $\mathcal{L}_\chi$ is a lisse sheaf at $x$, since we assumed that $f$ is coprime with $t(t - 1)$. We find
$$\varepsilon_x(\chi) = \varepsilon_x t.\mathcal{L}_\chi(x)^{a(\mathbf{P}_1(x), M(\mathbf{P}_1(x)) dt)}$$
by (11.9) with $F = \mathcal{L}_\chi$, where $\varepsilon_x = \varepsilon(\mathbf{P}_1(x), M, dt)$, which is independent of $\chi$. We further compute that
$$a(\mathbf{P}_1(x), M(\mathbf{P}_1(x)), dt) = -a(\mathbf{P}_1(x), \mathcal{F}(1/2)|\mathbf{P}_1(x), dt) = -(2 - 1 + 0) = -1$$
by (C.3) and (C.4), since $\mathcal{F}$ has drop 1 at $x$ (see, e.g., [68, p. 73]) and $dt$ is regular at $x$. Hence,
\begin{equation}
(11.11) \quad \varepsilon_x(\chi) = \varepsilon_x \prod_{z \in Z} \chi_z(z - x)^{-1}.
\end{equation}

Case 3. Let $x \in Z$. Then we can write
$$M \otimes \mathcal{L}_\chi = \mathcal{F}[1](1/2) \otimes \mathcal{L}^{(x)} \otimes \mathcal{L}_{\chi_x(t-x)} = (\mathcal{F}(1/2) \otimes \mathcal{L}^{(x)} \otimes \mathcal{L}_{\chi_x(t-x)})[1],$$
where $\mathcal{F}$ and $\mathcal{L}^{(x)}$ are both lisse sheaves at $x$. Applying (11.9) after an inversion due to the shift, we get
$$\varepsilon_x(\chi) = \varepsilon(\mathbf{P}_1(x), \mathcal{F}[1](1/2) \otimes \mathcal{L}^{(x)} \otimes \mathcal{L}_{\chi_x(t-x)}, dt)^{-1}$$
$$= \det(\text{Fr}_x | \mathcal{F}(1/2) \otimes \mathcal{L}^{(x)})^{-a(\mathbf{P}_1(x), \mathcal{L}_{\chi_x(t-x)}, dt)^{-2}}$$
where
$$a = a(\mathbf{P}_1(x), \mathcal{L}_{\chi_x(t-x)}, dt) = 1 + 0 - 0 = 1$$
if $\chi_x$ is non-trivial by (C.3) and (C.4) again.

We have
$$\det(\text{Fr}_x | \mathcal{F}(1/2) \otimes \mathcal{L}^{(x)}) = \frac{1}{|k|} \prod_{z \in Z} \chi_z(z - x)^2,$$
and by (C.9), we find that
$$\varepsilon(\mathbf{P}_1(x), \mathcal{L}_{\chi_x(t-x)}, dt) = \varepsilon_0(\mathbf{P}_1(x), \mathcal{L}_{\chi_x(t-x)}, dt) = \varepsilon_x(-1) \sum_{y \in k^x} \chi(y)\psi(y)$$
if $\chi_x$ is not trivial (here we also use the fact that $x \in k$).

These computations imply that
\begin{equation}
(11.12) \quad \varepsilon_x(\chi) = \prod_{\substack{z \in Z \setminus x \neq x}} \chi_z(z - x)^{-2} |k| \left( \sum_{y \in k^x} \chi(y)\psi(y) \right)^{-2},
\end{equation}
if $\chi_x$ is not trivial.

Case 4. Let $x = \infty$. Write $u = 1/t$, a uniformizer at $\infty$, so that $dt = -u^{-2}du$. Then $\mathcal{L}_\chi = \mathcal{L}^{(\infty)} \otimes \mathcal{L}_{\eta(u)}$ where
$$\mathcal{L}^{(\infty)} = \bigotimes_{z \in Z} \mathcal{L}_{\chi_z uz^{-1}}, \quad \eta = \prod_{z \in Z} \chi_z^{-1}.$$

153
The sheaf \( \mathcal{L}(\infty) \) is lisse at \( \infty \) and the local eigenvalue of Frobenius there is equal to \((-1)^{\deg(f)}\). On the other hand, we have \( M = \mathcal{F}[1](1/2) \), and \( \mathcal{F} \) is of rank 2, namely ramified at \( \infty \) with local monodromy isomorphic to \( \mathcal{L}_\lambda \otimes \text{Unip}(2) \), where \( \lambda \) is the Legendre character and \( \text{Unip}(2) \) is a unipotent Jordan block of size 2 (see, e.g., [68, p. 73]).

Computing first as in the previous case, we get

\[
\varepsilon_\infty(\chi) = \varepsilon(P^{1}(\infty), \mathcal{F}(1/2) \otimes \mathcal{L}(\infty) \otimes \mathcal{L}_\eta(u), -u^{-2}du)^{-1} = \det(\text{Fr}_\infty | \mathcal{L}(\infty))^{-a} \varepsilon(P^{1}(\infty), \mathcal{F}(1/2) \otimes \mathcal{L}_\eta(u), -u^{-2}du)^{-1}
\]

where

\[
a = a(P^{1}(\infty), \mathcal{F}(1/2) \otimes \mathcal{L}_\eta(u), -u^{-2}du) = a(P^{1}(\infty), \mathcal{F}(1/2) \otimes \mathcal{L}_\eta(u)) - 2 \times 2 = (2 + 0 - 2) - 4 = -4
\]

if \( \eta \) is non-trivial (see again (C.3) and (C.4)). Note then that

\[
\det(\text{Fr}_\infty | \mathcal{L}(\infty))^{-a} = \prod_{z \in \mathbb{Z}} \chi_z(-1)^4 = 1.
\]

The shape of the local monodromy and the multiplicativity property under extensions shows that if \( \lambda_2 \eta \) is not trivial, then the formula

\[
\varepsilon(P^{1}(\infty), \mathcal{F}(1/2) \otimes \mathcal{L}_\eta(u), -u^{-2}du) = \varepsilon(P^{1}(\infty), \mathcal{L}(\lambda_2 \eta)(u), -u^{-2}du)^{2}
\]

holds. Indeed, in this case, the stalk at \( \infty \) of \( \mathcal{F} \otimes \mathcal{L}_\eta \) and of its semisimplification both vanish, so that

\[
\varepsilon(P^{1}(\infty), \mathcal{F}(1/2) \otimes \mathcal{L}_\eta(u), -u^{-2}du) = \varepsilon_0(P^{1}(\infty), j_* \mathcal{F}(1/2) \otimes \mathcal{L}_\eta(u), -u^{-2}du),
\]

where \( \varepsilon_0 \) is the local factor defined by (C.5), and \( j \) is the inclusion of the generic point of \( P^{1}(\infty) \), and one can apply (C.6); compare [25, 8.12].

Let \( \beta \) be the character of the local field at infinity associated to \( \lambda_2 \eta \) by local class field theory. Using (C.8), we derive the formula

\[
\varepsilon(P^{1}(\infty), \mathcal{L}(\lambda_2 \eta)(u), -u^{-2}du) = \beta(-u^{-2})|k|^{-2} \varepsilon(P^{1}(\infty), \mathcal{L}(\lambda_2 \eta)(u), du).
\]

From (C.9), we deduce further that

\[
\varepsilon(P^{1}(\infty), \mathcal{L}(\lambda_2 \eta)(u), -u^{-2}du) = |k|^{-2} \sum_{y \in k^x} (\lambda_2 \eta)(y) \psi(y)
\]

if \( \lambda_2 \eta \) is non-trivial.

The final outcome is that

\[
(11.13) \quad \varepsilon_\infty(\chi) = |k|^4 \left( \sum_{y \in k^x} (\lambda_2 \eta)(y) \psi(y) \right)^{-2},
\]

if \( \eta \notin \{1, \lambda_2\} \).

We now simply combine the formulas (11.10), (11.11), (11.12) and (11.13) to conclude the proof, noting that the contribution of all \( x \in \mathbb{Z} \) involves the product

\[
\prod_{x \in \mathbb{Z}} \prod_{z \in \mathbb{Z}} \chi_z(z - x)^{-2} = \prod_{z \in \mathbb{Z}} \chi_z \left( \prod_{x \in \mathbb{Z}} (z - x)^{-2} \right).
\]

□
Remark 11.12. It it also certainly possible to perform this computation by automorphic methods (using the global case of the $\text{GL}_2$-Langlands correspondence over $k(t)$, first proved by Drinfeld). However, more general situations might be easier to handle using these geometric arguments.

Yet another possible approach, which would be well-suited for generalizations, would be to use Loeser’s general computation of the tannakian determinant for an arbitrary perverse sheaf on a torus $T$ (see [91, Th. 3.6.1]), which can be identified with an element of a group $H_{\text{int}}(T)$ which was computed by Gabber and Loeser, and is isomorphic to $T(\bar{k}) \times \mathbb{Z}^S$ for some explicit set $S$ (related to sub-tori of dimension 1 in $T$ and tame $\ell$-adic characters of $\mathbb{G}_m$). It would then be enough to show that there exists from $s \in S$ such that the $s$-component of $\det(M)$ is non-zero to deduce that $\det(M)$ has infinite order (without computing exactly the determinant). See Remark B.5 (2) for the case $T = \mathbb{G}_m$ of the formula of Gabber–Loeser for $H_{\text{int}}(T)$. 

155
CHAPTER 12

Equidistribution on abelian varieties

In this chapter, we consider some aspects of equidistribution on abelian varieties. We denote as before by $k$ a finite field, and by $\overline{k}$ an algebraic closure of $k$. We denote by $k_n$ the extension of degree $n$ in $\overline{k}$. The prime $\ell$ is different from the characteristic of $k$.

12.1. Equidistribution in the Jacobian of a curve

The main result of this section is a generalization of a theorem announced by Katz during a talk at ETH Zürich in November 2010 [67], answering a question of Tsimerman.

Let $C$ be a smooth projective geometrically connected curve of genus $g \geq 2$ over $k$, and let $A = \text{Jac}(C)$ be its Jacobian. We recall that $C$ may not have $k$-rational points but always has a $k$-rational divisor of degree one. We fix such a divisor $D$ and we denote by $s_D : C \hookrightarrow A$ the closed immersion obtained by sending a point $x$ to the class of the divisor $(x) - D$. Recall that the functor $s_D^* = s_D!$ preserves perversity (Corollary A.8).

**Theorem 12.1 (Katz).** Let $D$ be a divisor of degree one on $C$. Let $M_0$ be a geometrically simple perverse sheaf on $C$ of generic rank $r \geq 1$ which is pure of weight zero. Let $M = s_D^* M_0$ and let $d$ denote the tannakian dimension of $M$.

1. We have $d \geq (2g - 2)r + \sum_{x \in C(\overline{k})} \text{swan}(x) + \text{drop}(x) \geq (2g - 2)r$.
2. Assume that $C$ is hyperelliptic, that $D = (0_C)$ for some $k$-rational point $0_C \in C(k)$ fixed by the hyperelliptic involution $i$, and that $D(M_0)$ is geometrically isomorphic to $i^* M_0$. Then, up to conjugacy, there are inclusions $G_\text{geo} = G_\text{ari} = \text{Sp}_d \subset \text{O}_d$.
3. If $C$ is not hyperelliptic, or if $C$ is hyperelliptic but $D(M_0)$ is not geometrically isomorphic to $i^* M_0$, then there are inclusions $\text{SL}_d \subset G_\text{geo} \subset G_\text{ari} \subset \text{GL}_d$.

**Proof.** We write $s = s_D$ for simplicity. Since $A$ is an abelian variety, the dimension $d$ is the Euler–Poincaré characteristic of $M_\chi$ for any $\chi \in \hat{A}$ (see Proposition 3.21), in particular for the trivial character, which means that $d = \chi(A_\overline{k}, M) = \chi(C_\overline{k}, M_0)$. Write $M_0 = \mathcal{F}_0[1](1/2)$ for some middle extension sheaf $\mathcal{F}_0$ on $C$ of generic rank $r$; using the Euler–Poincaré characteristic formula on a curve (see (C.11), for instance), it follows that

\begin{equation}
\chi(C_\overline{k}, M_0) = \chi(C_\overline{k}, \mathcal{F}_0[1]) = (2g - 2)r + \sum_{x \in C(k)} \text{swan}_x(\mathcal{F}_0) + \text{drop}_x(\mathcal{F}_0) \geq (2g - 2)r.
\end{equation}

According to Proposition 9.10, (2), the embedding $s$ is a Sidon morphism if $C$ is not hyperelliptic, and is an $i$-symmetric Sidon morphism in the hyperelliptic situation of (2).

Suppose first that $C$ is not hyperelliptic. Using the fact that $d \geq 2$, we deduce from Proposition 9.7 that $\text{M}_4(G_\text{ari}) = 2$. Thus, by Larsen’s Alternative (Theorem 9.4, (3)), either $G_\text{ari}$ is...
virtually central, i.e. \( G_{ari}^M / G_{M}^ari \cap Z \) is finite, or \( G_{M}^ari \) contains \( SL_d \). Proposition 9.21 shows that the first case is not possible, since \( M_4(G_{M}^ari) = 2 \) is not the square of an integer. Then the fact that \( G_{M}^ari \) contains \( SL_d \) implies that \( G_{M}^geo \) also contains \( SL_d \) (indeed, the intersection \( G_{M}^geo \cap SL_d \) is a normal subgroup of \( G_{M}^ari \) by Proposition 3.38, and hence is a normal subgroup of \( SL_d \); it is therefore either equal to \( SL_d \), or is contained in the center \( \mu_d \); but since \( d \geq 2 \), the latter would imply that \( G_{M}^ari / G_{M}^geo \) is not abelian).

We now assume that \( C \) is hyperelliptic. First we consider the case when \( d \geq 3 \).

If \( D(M_0) \) is not geometrically isomorphic to \( i^*M_0 \), then Proposition 9.8, (2) implies that \( M_4(G_{M}^ari) = 2 \) since we assume that \( d \geq 3 \); as previously, we then conclude that \( G_{M}^ari \) contains \( SL_d \).

If the conditions of (2) hold, then the constant morphism \( (s \circ i) + s \) is given by

\[
s(i(x)) + s(x) = (x) + i(x) - 2(0_C) = 0,
\]

the identity element of \( A \). Proposition 9.8, (1) implies then that \( M \) is self-dual and has \( M_4(G_{M}^ari) = 3 \), again from our assumption that \( d \geq 3 \). We conclude in that case by Larsen’s Alternative (Theorem 9.4, (5)), combined with the fact that \( G_{M}^ari \) is infinite by Theorem 5.7.

There remains to consider the case when \( d = 2 \) (and \( C \) hyperelliptic). Since \( d = \chi(C, M_0) \), formula (12.1) shows that this situation can only occur if \( (g, r) = (2, 1) \) and if the sheaf \( \mathcal{F}_0 \) is lisse on \( C \). Thus the curve \( C \) has genus 2, and the sheaf \( \mathcal{F}_0 \) is a rank 1 sheaf corresponding to a character of the fundamental group of \( C \). As we will recall below in general, there exists then a character \( \chi_0 \in \hat{A}(k) \) such that \( \mathcal{F}_0 \) is geometrically isomorphic to \( s^*\mathcal{L}_{\chi_0} \) on \( C \). The duality condition \( M_0 \cong i^* D(M_0) \) is then always satisfied.

We claim that in this situation, the fourth moment \( M_4(G_{M}^ari) \) is still equal to 2. Indeed, from the proof of Proposition 9.8, we know that

\[
\frac{1}{|A(k_n)|} \sum_{\chi \in \hat{A}(k_n)} |S(M, \chi)|^4
\]

converges to 3 as \( n \to +\infty \). The contribution of the character \( \chi_0^{-1} \), which is the only ramified character, is

\[
\frac{1}{|A(k_n)|} |S(M, \chi_0^{-1})|^4 = \frac{1}{|A(k_n)|} \left| \sum_{x \in C(k_n)} t_{M_0}(x; k_n) \chi_0(x) \right|^4 = \frac{|C(k_n)|^4}{|k_n^2| |A(k_n)|}
\]

which converges to 1 as \( n \to +\infty \). We then conclude from Larsen’s Alternative that \( G_{M}^ari \) contains \( SL_2 = Sp_2 \).

**Remark 12.2.** (1) Note that the last case provides a concrete example where the limit

\[
\lim_{n \to +\infty} \frac{1}{|A(k_n)|} \sum_{\chi \in \hat{A}(k_n)} |S(M, \chi)|^4,
\]

exists, where the sum ranges over all characters, but its value is *not* the fourth moment of the standard representation of the tannakian group (see Remark 9.9).

(2) If the curve \( C \) has gonality at least 5, then the inclusions

\[
SL_d \subset G_{M}^geo \subset G_{M}^ari \subset GL_d
\]

can be deduced without appealing to Proposition 9.21. Indeed, the immersion \( s_D \) is then a 4-Sidon morphism by Proposition 9.10, (3), so we deduce from; Proposition 9.7, (2) that \( G_{M}^ari \) (and hence also \( G_{M}^geo \), as before) contains \( SL_d \). (Precisely, we are in the excluded case of this statement, but
we can observe that there are only finitely many ramified characters here, and that the assumption implies that the genus of $C$ is at least five, so that the contribution to the 8-th moment of the ramified characters is
\[ \ll \frac{1}{|k_n|^g} |k_n|^{8/2} \rightarrow 0, \]
so that we do obtain the correct 8-th moment.)

**Remark 12.3.** In characteristic zero, Krämer and Weissauer [83]) have obtained closely related results, using more geometric methods in the case of the object $M = \mathfrak{s}_{D,\mathbf{Q}_\ell}[1]$.

We now explain how Theorem 12.1 answers a question of Tsimerman, which was Katz’s original motivation. Let $\varrho: \pi_1(C)^{ab} \rightarrow \mathbf{C}^\times$ be a character of finite order. By the Riemann hypothesis for curves over finite fields, the Artin L-function $L_C(g, s)$ is a polynomial of degree $2g - 2$ in the variable $T = q^{-s}$ all of whose reciprocal roots have absolute value $\sqrt{q}$. We can then write
\[ L(\varrho, T/\sqrt{q}) = \det (1 - T\Theta_{C/k, \varrho}) \]
for a unique conjugacy class $\Theta_{C/k, \varrho}$ in the unitary group $U_{2g-2}(\mathbf{C})$.

**Question (Tsimerman).** How are these conjugacy classes distributed as $\varrho$ varies?

From now on, we shall normalize the characters as follows: we fix a divisor $D = \sum n_ix_i$ of degree one on $C$ and we only consider those characters $\varrho$ satisfying
\[ \prod \varrho(\text{Fr}_{\kappa(x_i), x})^{n_i} = 1. \]
Through the isomorphism $\pi_1(C)^{ab} \simeq \pi_1(A)$ induced by $s_D: C \rightarrow A = \text{Jac}(C)$, such normalized characters correspond to characters $\varrho: \pi_1(A) \rightarrow \mathbf{C}^\times$ satisfying $\varrho(\text{Fr}_{k, 0, A}) = 1$. Since they are in addition supposed to be of finite order, they arise via the Lang isogeny from the elements of $\hat{A}(k)$. Replacing $k$ with $k_n$, we obtain the corresponding characters in $\hat{A}(k_n)$. Thus the following statement answers Tsimerman’s question when considering conjugacy classes associated to normalized characters over $k_n$ and taking $n \rightarrow +\infty$.

**Corollary 12.4.** Let $C$ be a smooth projective geometrically connected curve of genus $g \geq 2$ over $k$ with jacobian $A$.

1. If $C$ is hyperelliptic, the hyperelliptic involution has a fixed $k$-point $0 \in C(k)$, and we use this point to define the embedding $C \rightarrow A$, then the conjugacy classes $(\Theta_{C/k, \chi})_{\chi \in \hat{G}(A_n), \chi \neq 1}$ are conjugacy classes in $U_{\text{Sp}}_{2g-2}(\mathbf{C})$ and become equidistributed with respect to the image of the Haar probability measure on the set of conjugacy classes.

2. If $C$ is not hyperelliptic and $(2g-2)D$ is a canonical divisor on $C$, then the conjugacy classes $(\Theta_{C/k, \chi})_{\chi \in \hat{A}(k_n), \chi \neq 1}$ are conjugacy classes in $U_{2g-2}(\mathbf{C})$ and become equidistributed with respect to the image of the Haar probability measure on the set of conjugacy classes.

**Proof.** Consider the weight zero perverse sheaf $M_0 = \overline{Q}_\ell(1/2)[1]$ on $C$ and set $M = \mathfrak{s}_{D, M_0}$. For each rank one $\ell$-adic lisse sheaf $\mathcal{L}$ on $A$, there are isomorphisms
\[ \text{H}^i(A_k, M \otimes \mathcal{L}) \simeq \text{H}^i(A_k, \mathfrak{s}_{D^*}(M_0 \otimes \mathfrak{s}_{D^*}\mathcal{L})) \simeq \text{H}^i(C_k, M_0 \otimes \mathfrak{s}_{D^*}\mathcal{L}) \simeq \text{H}^{i+1}(C_k, \mathfrak{s}_{D^*}\mathcal{L}(1/2)) \]
by the projection formula and the exactness of $\mathfrak{s}_{D^*}$. It follows that $M$ has tannakian dimension
\[ -\chi(C_k, \mathfrak{s}_{D^*}\mathcal{L}) = 2g - 2, \]
and moreover that all non-trivial characters are unramified for $M$ (since we are considering an abelian variety). By Theorem 4.11, it suffices therefore to prove that the arithmetic and geometric tannakian groups of $M$ coincide and are equal to $\text{Sp}_{2g-2}$ in case (1) and to $\text{SL}_{2g-2}$ in case (2).
Assume $C$ is hyperelliptic with hyperelliptic involution $i$. Then the sheaf $M_0$ is geometrically isomorphic to $i^* D(M_0)$ and, because of the shift by 1 in the definition of $M_0$, the corresponding self-duality is symplectic. Therefore, if in addition we assume that $i$ has a fixed $k$-point $0 \in C(k)$, which we use as divisor $D$, Theorem 12.1 (2) gives the equality $G_M^{\text{geo}} = G_M^{\text{ari}} = \text{Sp}_{2g-2}$.

If $C$ is not hyperelliptic and $(2g-2)D$ is a canonical divisor on $C$, in view of Theorem 12.1 (3), it suffices to show that the arithmetic group $G_M^{\text{ari}}$ lies in $\text{SL}_{2g-2}$. For this, we compute the determinant of the action of Frobenius on $H^1(C_\bar{k}, \mathcal{L}(1/2))$. Since this cohomology is even-dimensional, this is also the determinant of $-\text{Fr}_k$, which is the constant in the functional equation for the $L$-function of $\mathcal{L}(1/2)$. By a classical result of Weil [111], in the case of $\mathcal{L}$ this constant is given by $q^{1-g} \varrho_{\mathcal{L}}(\text{can})$ for a canonical divisor can, where $\varrho_{\mathcal{L}}$ is the character associated to $\mathcal{L}$, which factors through the jacobian. Taking the half-Tate twist into account, along with the fact that $\varrho_{\mathcal{L}}(\text{can}) = 1$ since $(2g-2)D$ is a canonical divisor and characters are normalized to take the value 1 at $D$, it follows that the determinant is trivial, as claimed.

We conclude this section by a (partial) generalization of Theorem 12.1 to the setting of generalized jacobians arising in geometric class-field theory. This gives a natural example of an application of our results where the algebraic group $G$ is not restricted to being either a torus, an abelian variety or a unipotent group, but may involve all three of these fundamental building blocks (see Remark 9.13). For simplicity, we will only deal with the case where $C$ is not hyperelliptic.

**Theorem 12.5.** Assume that the curve $C$ is not hyperelliptic. Let $S$ be an effective divisor on the curve $C$. Let $U$ be the complement of the support of $S$ in $C$. Let $D$ be a divisor of degree one on $U$. Let $J_S$ be the generalized jacobian of $C$ relative to the divisor $S$, and let $s_D: U \to J_S$ be the natural immersion defined by $x \mapsto (x) - D$.

Let $M_0$ be a semiperverse object on $U$, mixed of weights $\leq 0$ and put $M = s_D! M_0$. Let $d$ be the tannakian dimension of the semisimplification $\tilde{M}$ of the part of $\mathcal{P}H^0(M)$ which is pure of weight 0. Assume that $\tilde{M}$ is non-zero.

Then we have $d \geq 2$, and either the arithmetic tannakian group of $\tilde{M}$ contains $\text{SL}_d$ or $G_M^{\text{ari}}$ is virtually central in $\text{GL}_d$.

**Proof.** We note that $M$ is a semiperverse object on $J_S$ since $s_D$ is quasi-finite, and is mixed of weights $\leq 0$ by the Riemann Hypothesis.

To check that $d \geq 2$, we use the general Euler–Poincaré characteristic formula (see Theorem C.2) as in (12.1), to conclude. We then need only observe that $s_D$ is a Sidon morphism by Proposition 9.12, and apply Larsen’s Alternative.

**Remark 12.6.** (1) Since we do not know in general if perverse sheaves on the group $J_S$ are generically unramified, the corresponding equidistribution statement is currently restricted to the distribution of the arithmetic Fourier transforms

$$\sum_{x \in U(k_n)} t_M(x; k_n) \chi(x)$$

for $\chi \in \mathcal{J}_S(k_n)$.

(2) Again because the group $J_S$ is a priori fairly arbitrary here, we can not exclude the possibility that $G_M^{\text{ari}}$ is virtually central (e.g., finite), since we do not have currently a general version of Proposition 9.21. (In our case, since the jacobian of $C$ is a non-trivial quotient of $J_S$, we can expect that the statement should indeed extend.)

---

\[1\] Which can also easily be recovered from the theory of local constants, applying the results of Deligne and Laumon (see Appendix C).
12.2. The intermediate jacobian of a cubic threefold

Our second application involving abelian varieties is related to a very classical and important construction in algebraic geometry, that of the intermediate jacobian of a smooth cubic threefold, which was used by Clemens and Griffiths to prove that these threefolds, over $\mathbb{C}$, are not rational (although they are unirational).

The geometric setting, which over finite fields goes back at least to the work of Bombieri and Swinnerton-Dyer \cite{8} (computing the zeta function of smooth cubic threefolds over finite fields) is the following.

Let $k$ be a field of characteristic different from 2, and let $X \subset \mathbb{P}^4_k$ be a smooth cubic threefold over $k$. We denote by $F(X)$ the Fano scheme of lines in $X$, which is a smooth projective and geometrically connected surface over $k$ (see, e.g., \cite[§4]{4} or \cite[Lem. 3]{8}, or \cite[Cor. 1.12, Th. 1.16]{3}; this uses the fact that the characteristic is different from 2). Let then $A(X)$ be the Albanese variety of $F(X)$, which is known to be isomorphic to the Picard variety of $F(X)$ (see, e.g. \cite[Cor. 4.3.3]{57}).

It has dimension 5, and if the base field is contained in $\mathbb{C}$, then the analytification of $A(X)$ is canonically isomorphic to the intermediate jacobian $J(X)$ of Griffiths, which is defined analytically in terms of Hodge theory (this is due to Murre; see \cite[Prop. 9]{4}).

The Albanese morphism $s: F(X) \to A(X)$ is a closed immersion, according to a theorem of Beauville \cite[p. 201, cor.]{4}. If we view $A(X)$ as the Picard variety, then the morphism $s$ can be identified geometrically with the map sending a line $l \in F(X)$ to the divisor defined by the curve $C_s$ which is the Zariski-closure in $F(X)$ of the set of lines $l' \neq l$ such that $l' \cap l$ is not empty.

The problem we consider is then the following: if $k$ is a finite field of odd characteristic, what is the arithmetic tannakian group of the perverse sheaf $M = s^* \overline{\mathbb{Q}}_l[2](1)$ on $A(X)$? (It is perverse because $s$ is a closed immersion, as in previous similar examples.) The corresponding exponential sums are then

$$S(M, \chi) = \frac{1}{|k_n|} \sum_{l \in F(X)(k_n)} \chi(s(l))$$

for a character $\chi \in \hat{A}(X)(k_n)$.

Up to correcting a small oversight, the following answer is the analogue over finite fields of a result of Krämer over $\mathbb{C}$ (see \cite[Th. 2]{82}).

**Proposition 12.7.** Let $k$ be a finite field of characteristic different from 2. Let $X$ be a smooth cubic threefold over $k$, and denote by $F(X)$ the Fano scheme of lines in $X$, by $A(X)$ the Albanese variety of $F(X)$, and by

$$s: F(X) \to A(X)$$

the natural closed immersion.

Let $\ell$ be a prime different from the characteristic of $k$, and let $M$ be the object $M = s_* \overline{\mathbb{Q}}_l[2](1)$ on $A(X)$. The connected derived subgroup of the arithmetic tannakian monodromy group of the object $M$ of the category $\mathfrak{P}^{\text{art}}(A(X))$ is isomorphic to the exceptional group $E_6$.

For the proof, we will use the following lemma, whose proof was communicated to us by Beauville.

**Lemma 12.8 (Beauville).** With notation as above, there is no $x \in A(X)$ such that $-s(F(X)) = x + s(F(X))$, and there is no non-zero $x \in A(X)$ such that $s(F(X)) = x + s(F(X))$.

**Proof.** We argue by contradiction.
For the first assertion, if \( x \) existed such that \( -s(F(X)) = x + s(F(X)) \), then the involution \( a \mapsto -x - a \) of \( A(X) \) would induce an involution \( i \) of the variety \( F(X) \) with a finite number of fixed points. The quotient variety \( F(X)/i \) has then only isolated ordinary double points as singularities, and in particular its canonical divisor \( K_{F(X)/i} \) is a Cartier divisor. Since the projection \( p: F(X) \rightarrow F(X)/i \) is étale outside of the set of fixed points, the canonical divisor of \( F(X) \) is \( K = p^*(K_{F(X)/i}) \). This implies that \( K^2 = 2(K_{F(X)/i})^2 \) is even. However, it is known that \( K^2 = 45 \), which is odd (see, e.g., [57, Prop. 4.6]).

For the second assertion, note that \( s(F(X)) = x + s(F(X)) \) would imply that \( s(F(X)) - s(F(X)) = x + s(F(X)) - s(F(X)) \), so that the theta divisor \( \Theta(X) = s(F(X)) - s(F(X)) \) satisfies \( \Theta(X) = x + \Theta(X) \). However, Beauville [4, §3, Prop. 2] showed that \( \Theta(X) \) is smooth except for a single singularity, so this equality can only happen if \( x = 0 \) \( \square \).

**Remark 12.9.** The cohomological analogue of this proposition is not true: for \( \varepsilon \in \{-1, 1\} \), the cohomology class of \( \varepsilon s(F(X)) \) is \( \Theta^3/6 \), where \( \Theta \) is the cohomology class of the symmetric theta divisor \( s(F(X)) - s(F(X)) \).

We now give a proof of Proposition 12.7 adapting Krämer’s argument over \( \mathbb{C} \), the key point being the recognition criterion of \( E_6 \) in Proposition 9.18.

**Proof.** Since \( F(X) \) is a smooth, projective and geometrically connected surface, the object \( M \) is a simple perverse sheaf on \( A(X) \). The tannakian dimension of \( M \) is equal to the Euler–Poincaré characteristic of \( M \) over \( \bar{k} \) (Proposition 3.21), which is equal to the Euler–Poincaré characteristic of the Fano surface \( F(X) \), which is 27 (a result of Fano, see, e.g., [3, Prop. 1.23]).

Let \( \Theta(X) \) be the theta divisor \( s(F(X)) - s(F(X)) \) in \( A(X) \), and \( i: \Theta(X) \rightarrow A(X) \) the closed immersion. The object \( M \ast M^\vee \) contains the object \( N = i_*\mathbb{Q}_l[1] \) by the decomposition theorem (see [82, proof of Th. 2]). This is also a simple perverse sheaf since \( \Theta \) is a geometrically irreducible divisor (see, e.g., [4, Prop. 2]). The tannakian dimension of \( N \) can be computed as in [82, Cor. 6] (or by lifting to characteristic 0, as can be done as in [8, Proof of Lemma 5]), and is equal to 78.

To conclude using Proposition 9.18, applied to the connected derived subgroup \( G \) of \( G_\text{M} \), it suffices therefore to check that \( G \) still acts irreducibly on the 27-dimensional representation corresponding to \( M \).

To see this, note that the neutral component \( (G_\text{M})^\circ \) acts irreducibly by Corollary 5.9 combined with Lemma 12.8. Then its derived group \( G \) must also act irreducibly since

\[
(G_\text{M})^\circ = C \cdot G
\]

for some torus \( C \), which is central by irreducibility. \( \square \)

It is natural to ask whether this proposition can also be proved using the fourth moment criterion of Proposition 9.19 instead of Krämer’s criterion.

We have not yet succeeded in doing so, but we can show that the question translates to an interesting geometric property of the cubic threefolds. Conversely, this property follows in fact from the previous proof, as we will now explain.

In order to apply Proposition 9.19, we need to check that the object \( M \) is not self-dual, that it has tannakian dimension 27 and that its fourth moment is \( M_4(G_\text{M}) = 3 \).

Lemma 12.8 implies that \( M \) is not self-dual. The second property is derived as in the beginning of the previous proof. Now we attempt to compute the fourth moment.
Thus $S$ is a smooth cubic surface, and the lines and hence $\eta$ are contained in the intersection $S$ of $X$ and of the projective 3-space spanned by $\eta$. We then deduce that $\tilde{f}$ is generically finite of degree 5. By the Chebotarev Density Theorem (see, e.g., [72, Th. 9.7.13]) it follows that

$$\lim_{n \to +\infty} \frac{1}{|k_n|^4} \sum_{l_1 \neq l_2 \in F(k_n)} \tilde{N}(l_1, l_2)$$

is equal to the number of orbits of the Galois group of the Galois closure of $\tilde{f}$ in its permutation representation on the generic fiber of $\tilde{f}$.

The generic point $\eta$ of $F^2$ is a pair of two disjoint lines $\eta = (\tilde{s}_1, \tilde{s}_2)$. Beauville showed that the points $(\tilde{s}_3, \tilde{s}_4) \in F^2$ such that $(\tilde{s}_1, \tilde{s}_2, \tilde{s}_3, \tilde{s}_4)$ is in the fiber over $\eta$ are such that the lines $\tilde{s}_3$ and $\tilde{s}_4$ are contained in the intersection $S$ of $X$ and of the projective 3-space spanned by $(\tilde{s}_1, \tilde{s}_2)$. Thus $S$ is a smooth cubic surface, and the lines $\tilde{s}_3$ and $\tilde{s}_4$ are elements of the set $\Lambda$ of the five lines.
in S intersecting both $\tilde{s}_1$ and $\tilde{s}_2$; for these geometric facts, see [4, p. 203, rem. 2] or [57, proof of Cor. 4.3.9].

We claim that the subgroup of the Galois group of the 27 lines which fixes the two lines $\tilde{s}_1$ and $\tilde{s}_2$ is the Galois group of the set of seven lines $\{\tilde{s}_1, \tilde{s}_2\} \cup \Lambda$ (see Lemma 12.11 below). Now it follows from the work of Harris on Galois groups of enumerative problems (see [54, p. 718]) that this permutation representation is indeed transitive, in fact that it has image isomorphic to the whole symmetric group $S_5$, if we take the base field to be $\mathbb{C}$ and the cubic threefold to be general.

One may expect this to also be true in our situation:

– the restriction of the base field should not be problematic (indeed, the fact that the “generic” Galois group of the 27 lines on a smooth cubic surface is isomorphic to the Weyl group of $E_6$, which is the starting point of Harris’s work, is known in all odd characteristics, by work of Achter [2, Prop. 4.8]);

– the (four-dimensional) family of hyperplane sections that we consider is dominant over the (also four-dimensional) space of hyperplane sections of the cubic hypersurface $X$ (indeed, for any hyperplane $H$ in $\mathbb{P}^4$ intersecting $X$ in a smooth hyperplane, we can pick two distinct lines $(l_1, l_2)$ in $X \cap H$, and the corresponding section is $H \cap X$);

– and the family of all hyperplane sections of $X$ is probably general enough for the result of Harris to extend. (This is in fact the most delicate point.)

If we assume that this expectation holds for $X$, then we would deduce that

$$\lim_{n \to +\infty} \frac{1}{|k_n|^4} \sum_{l_1 \neq l_2 \in \mathbb{F}(k_n)} \tilde{N}(l_1, l_2) = 1$$

holds, and hence conclude that

$$\lim_{n \to +\infty} \frac{1}{|k_n|^4} \sum_{(l_1, l_2) \in \mathbb{F}(k_n)^2} N(l_1, l_2) = 3.$$ 

Under this assumption, we therefore derive from Proposition 9.3 that $M_4(G_{\text{ari}}) \leq 3$. Since $M$ is not of tannakian dimension 1, the fourth moment is equal to either 2 or 3. We can at least partially exclude the first possibility as follows:

(1) For “most” cubic threefolds, the abelian variety $A$ is absolutely simple (see Lemma 12.12 below for a precise statement). In this case, there are only finitely many characters $\chi \in \hat{A}$ which are not weakly-unramified, and for which

$$|S(M, \chi)| = \left| \frac{1}{|k_n|} \sum_{x \in \mathbb{F}(k_n)} \chi(s(x)) \right| \ll |k_n|,$$

so that

$$\frac{1}{|A(k_n)|} \sum_{\chi \notin \text{irr}(A)(k_n)} |S(M, \chi)|^4 \ll \frac{|k_n|^4}{|k_n|^6} \to 0$$

as $n \to +\infty$, and from Proposition 9.3, the computation we have performed actually means that the fourth moment is equal to 3.

(2) We may use the beginning of Krämer’s proof to deduce that $M \ast M^\vee$ contains an irreducible summand of dimension 78, which excludes the possibility that the fourth moment be equal to 2.
So under the above assumptions, we conclude that $M_4(M_{\text{Gari}}) = 3$ and we can then apply Proposition 9.19 (as in the previous argument, we use Corollary 5.9 to deduce that the neutral component of $M_{\text{Gari}}$ still acts irreducibly).

Now, going backwards, if we use Proposition 12.7, then we know that the fourth moment of $M_{\text{Gari}}$ is equal to 3, since the tannakian group is $E_6$. It follows that, at least in the first of the above two situations, the limit formula (12.2) must be true.

**Remark 12.10.** In contrast with Theorem 12.1, Proposition 12.7 will not extend to compute the fourth moment for perverse sheaves of the form $s^*M$ for a more general simple perverse sheaf $M$ on $F(X)$. One can expect that, in this case, the fourth moment should be equal to 2, but this seems difficult to prove.

We now state and prove the two lemmas we used above. The first one is certainly a standard fact in the study of the 27 lines.

**Lemma 12.11.** Let $S$ be a general smooth cubic hypersurface in $\mathbb{P}^3$ over an algebraically closed field. Let $l_1$ and $l_2$ be two disjoint lines in $S$. Let $\Lambda$ be the set of the five lines in $S$ intersecting both $l_1$ and $l_2$. Any Galois-automorphism of the twenty seven lines that fixes the lines in $\{l_1, l_2\} \cup \Lambda$ is the identity.

**Proof.** The key point in this computation is the fact that no line on $S$ is disjoint from all lines in $\Lambda$. More precisely, we use the classical description of $S$ as a blow-up of $\mathbb{P}^2$ in six points which are in general position (see, e.g., [57, Prop. 3.2.3]), and the resulting partition of the 27 lines in subsets

$$E_1, \ldots, E_6$$

$$L_{ij}, \quad 1 \leq i < j \leq 6$$

$$L_1, \ldots, L_6,$$

with incidences described as follows:

$$E_i \cap L_j \neq \emptyset$$

if and only if $i \neq j$,

$$E_i \cap L_{i,j} \neq \emptyset$$

for any $j$,

$$L_i \cap L_{i,j} \neq \emptyset$$

for any $j$,

$$L_{i,j} \cap L_{k,l} \neq \emptyset$$

for any $j$,

$$L_{i,j} \cap L_{k,l} \neq \emptyset$$

for any $j$,

all other pairs of lines being disjoint (see, e.g., [57, Rem. 3.2.4, 3.3.1]).

We choose the blow-up, as we may, so that $l_1 = E_1$ and $l_2 = E_2$ (see [57, 3.3.2]). We then have $\Lambda = \{L_{12}, L_3, L_4, L_5, L_6\}$.

Let $\sigma$ be a Galois automorphism which fixes the seven given lines. Since $\sigma$ respects incidence relations, we see:

1. For any $i$, we have $\sigma(E_i) = E_i$. Indeed, assume that $i = 3$ for simplicity, since all cases are similar. Then $E_3$ meets $L_4, L_5, L_6$, which implies that $\sigma(E_3)$ also intersects these three lines. But the only lines with this property are $E_1, E_2$ and $E_3$; since $\sigma$ fixes the first two of these, we have $\sigma(E_3) = E_3$.

2. For any $i$, we have $\sigma(L_i) = L_i$. Indeed, assume that $i = 1$; from the previous point, the lines $L_{12}, E_2, \ldots, E_6$, which all meet $L_1$, are fixed by $\sigma$, so that $\sigma(L_1)$ fixes all of them. We see that the only line with this property is $L_1$, so that $\sigma(L_1) = L_1$.

3. For any $i < j$, we have $\sigma(L_{i,j}) = L_{i,j}$. We consider the example of $L_{1,3}$, the other cases being similar. The lines $E_1, E_3, L_1, L_3$ all meet $L_{1,3}$, and hence (by the first two points)
also intersect $\sigma(L_{1,3})$. But this means that $\sigma(L_{1,3})$ must of one of the $L_{i,j}$, and the only one that has the desired property is $L_{1,3}$.

\[\square\]

The second lemma concerns the “generic” simplicity of the intermediate jacobian. Explicit examples that show that this property is not always valid are given for instance by Debarre, Laface and Roulleau [24, Cor. 4.12]; for the Fermat threefold

\[x_0^3 + \cdots + x_4^3 = 0\]

over $\mathbb{F}_p$, with $p \geq 5$, the intermediate jacobian is isogenous to $E^5$, where $E$ is the Fermat curve $y_0^3 + y_1^3 + y_2^3 = 0$.

**Lemma 12.12.** Let $k$ be a finite field of characteristic $p > 11$. Let $\mathcal{M}$ be the coarse moduli space of smooth projective cubic threefolds over $k$. For any integer $n \geq 1$, let $\mathcal{M}_s(k_n)$ be the subset of $X \in \mathcal{M}(k_n)$ such that the abelian variety $A(X)$ is simple over $k_n$.

There exists $\delta > 0$ such that the asymptotic formula

\[|\mathcal{M}_s(k_n)| = |\mathcal{M}(k_n)| \left(1 + O(|k_n|^{-\delta})\right)\]

holds for $n \geq 1$.

**Proof.** Fix a prime $\ell$ invertible in $k$. Let $\mathcal{F}$ be the lisse $\ell$-adic sheaf on $\mathcal{M}$ parameterizing the cohomology group $H^1(A(X)_{\overline{k}}, \mathbb{Q}_{\ell})$. The geometric monodromy group of $\mathcal{F}$ is the symplectic group $\text{Sp}_{10}$ by a result of Achter [2, Th. 4.3] (based on semicontinuity of monodromy and the extension to positive odd characteristic of a result of Collino [20] over $\mathbb{C}$, which states that the Zariski-closure of the image of $\mathcal{M}$ in the moduli space $\mathcal{A}_5$ of principally polarized abelian varieties of dimension 5 contains the locus $\mathcal{H}_5$ of jacobians of hyperelliptic curves of genus 5).

Using the method in [76, §6, §8], this implies that there exists $\delta > 0$ such that the set $\mathcal{M}_i(k_n)$ of threefold $X \in \mathcal{M}(k_n)$ for which the characteristic polynomial of Frobenius acting on $H^1(A(X)_{\overline{k}}, \mathbb{Q}_{\ell})$ is irreducible in $\mathbb{Q}[X]$ satisfies the asymptotic

\[|\mathcal{M}_i(k_n)| = |\mathcal{M}(k_n)| \left(1 + O(|k_n|^{-\delta})\right)\]

for $n \geq 1$, and one deduces the lemma since $\mathcal{M}_i(k_n) \subset \mathcal{M}_s(k_n)$. \[\square\]

**Remark 12.13.** A qualitative form of the result, namely the equality

\[\lim_{n \to +\infty} \frac{|\mathcal{M}_s(k_n)|}{|\mathcal{M}(k_n)|} = 1,\]

can be proved, mutatis mutandis, for finite fields of all odd characteristic. It also possible to improve this estimates to obtain absolute simplicity.
CHAPTER 13

“Much remains to be done”

We conclude this book with a selection of open problems (related to the results of this text) and questions (concerning potential generalizations and more speculative possibilities).

13.1. Problems

(1) Prove a version of the vanishing theorem where the size of the exceptional sets is controlled by the complexity in all cases, and moreover where those sets have a clear algebraic or geometric structure (similar to that of tacs for tori and abelian varieties).

(2) Prove that any object is generically unramified for a general group, or find a counterexample to this statement.

(3) Establish functoriality properties relating tannakian groups of $M$ on $G$ (resp. $N$ on $H$) with those of $f_* M$ (resp. of $f^* N$) when we have a morphism $f : G \to H$ of commutative algebraic groups.

(4) Study the situation in families over a base like $\text{Spec}(\mathbb{Z})$.

(5) Find additional and robust tools to compute the tannakian group, or at least to determine some of its properties, which are applicable when Larsen’s Alternative is not. In particular, find analogues (if they exist) of the local monodromy techniques for the Fourier transform on $G_a$ (i.e., of the local Fourier transform functors of Laumon).

(6) Construct interesting concrete perverse sheaves where the tannakian group is an exceptional group (Katz has constructed examples involving $G_2$, for $G_a$ [61, Th. 11.1], $G_m$ [68, Ch. 26, 27] and on some elliptic curves [70, Th. 4.1]; automorphic methods lead to the other exceptional groups in the case of $G_a$, as shown by Heinloth, Ngô and Yun [56]).

(7) Find further applications!

13.2. Questions

Many of the following questions are rather speculative and much more open-ended than the problems above. They may not have any interesting answer, but we find them intriguing.

(1) For a given $G$, what are the tannakian groups that may arise?

This is motivated in part by the striking difference concerning finite groups between $G_a$ and $G_m$ or abelian varieties. In the former case, the solution of Abhyankar’s Conjecture gives a characterization of which finite groups will appear, and a recent series of works of Katz, Rojas-Léon and Tiep has shown that there are many possibilities, even when one restricts attention to Fourier transforms of general hypergeometric sheaves (see for instance [73]) and $G_m$. On the other hand, we have already mentioned that Katz proved that finite cyclic groups are the only possible finite geometric tannakian groups on $G_m$, and Theorem 5.7 implies a similar statement for arithmetic tannakian groups on abelian varieties.
(2) For a given group $G$, if $M$ is a semisimple perverse sheaf associated to a semisimple lisse sheaf $\mathcal{F}$ on an open dense subset of $G$, what (if any) are the relations between the “ordinary” monodromy group $G$ of $\mathcal{F}$ and its tannakian groups?

In particular, suppose that $\mathcal{F}$ has finite monodromy group; what constraints does that impose on the tannakian group of $M$? We note that there is one “obvious” relation: the tannakian group acts irreducibly on its standard representation if and only if the lisse sheaf $\mathcal{F}$ is irreducible.

Since this last fact amounts to the discrete Plancherel formula, or equivalently to a relation between the second moments of both groups, a more specific question could be: are there non-trivial inequalities between the moments of the monodromy group of $\mathcal{F}$ and those of the tannakian group? For instance, does there exist a constant $c \geq 0$, independent of the size of the finite field $k$, such that

$$M_4(G_{\text{ari}}) \leq cM_4(G), \quad \text{and (or)} \quad M_4(G) \leq cM_4(G_{\text{ari}})?$$

One can get trivial bounds, similar to the bounds for the norm of the discrete Fourier transform on $G(k_n)$ when viewed as a map from $L^{2m}(G(k_n))$ to $L^{2m}(G(k_n))$ for $m > 1$ and $n$ varying, but this norm has been determined by Gilbert and Rzeszotnik [49, Th. 2.1] and depends on $n$.

(3) Can one construct a “natural” fiber functor $\omega$ on the tannakian category for $G$, similar to Deligne’s fiber functor for $G_m$?

This would lead to a definition of Frobenius conjugacy classes for all characters (by considering for any $\chi$ the conjugacy class in $G_{\text{ari}}$ corresponding to the fiber functor defined by $M \mapsto \omega(M_\chi)$), and potentially provide useful extra information to help determine the tannakian group. But note that this is not even clear in the case of $G_\alpha$.

(4) Can one find an a priori characterization of the families $(f_n)_{n \geq 1}$, where $f_n : \hat{G}(k_n) \to \mathbb{C}$ is a function, that arise as the arithmetic Fourier transforms of trace functions of complexes, or of perverse sheaves, on $G$?

More generally, is there a natural “geometric” object, with appropriate notions of sheaves, etc, on the “space” of characters of $G$? A crucial test for such a geometric interpretation of the discrete Fourier transforms would be the definition of an inverse transform.

This geometric description exists when $G$ is unipotent, since the Serre dual $G^\vee$ is also a commutative algebraic group, and the Fourier transform is defined as a functor from $D_c^b(G)$ to $D_c^b(G^\vee)$, but such a strong “algebraicity” property does not hold for other commutative algebraic groups (see for instance [14, Example 1.8], or Remark 5.3).

There are however some hints in a more positive direction:

(a) Gabber and Loeser [46, Th. 3.4.7] have characterized perverse sheaves on tori in terms of the structure of their (coherent) Mellin transforms (which can also be defined for semiabelian varieties), and Loeser [91, Ch. 4] has defined a variant over finite fields taking the Frobenius automorphism into account.

It would be of considerable interest to understand better the (essential) image of these Mellin transforms, and to obtain a geometric form of Mellin inversion in this context.

(b) Considering the well-established analogy of $\ell$-adic sheaves with $\mathcal{D}$-modules (the basic setup of Katz’s work [62]), it is well-understood in the complex setting that the Mellin transform of a $\mathcal{D}$-module is a difference equation (e.g., the Mellin transform $\Gamma(s) = s\Gamma(s)$ of the exponential satisfies the difference equation $\Gamma(s + 1) = s\Gamma(s)$); see for instance the paper of Loeser and Sabbah [92].
(5) Is there an analogue theory for non-commutative algebraic groups?

For instance, let $G$ be a reductive group over a finite field $k$, such as $\text{SL}_d(k)$. Deligne–Lusztig Theory parameterizes the irreducible representations of $G(k_n)$ (or some other more convenient basis of the $\ell$-adic representation ring) in terms of pairs $(\mathbf{T}, \theta)$ of a maximal torus of $G$ over $k$ and a character $\theta$ of $\mathbf{T}(k)$ (see for instance [18, Ch. 7]), and the corresponding series of representations have (essentially) constant dimension as $\theta$ varies, so that the character values in such series are suggestively sums of a fixed number of roots of unity. The theory of character sheaves of Lusztig gives a geometric form of this theory.

Are there equidistribution statements for the Fourier coefficients of suitably algebraic conjugacy-invariant functions on $G(k_n)$? In the case of characteristic functions of conjugacy classes, this might lead to interesting consequences concerning the error term in the Chebotarev Density Theorem for Galois extensions with Galois group of the form $G(k_n)$.

In the case of (possibly non-commutative) unipotent groups, the Serre dual still exists as a unipotent group; a theory of character sheaves, and of the Fourier transform has been studied by Lusztig and Boyarchenko–Drinfeld (see for instance the survey [14]).

(6) Is there an analogue of automorphic duality for other groups than $\mathbb{G}_a$?

What we mean by this is the following: in the case of a simple middle extension sheaf $\mathcal{F}$ on $\mathbb{G}_a$ over a finite field $k$ that is pure of weight zero and not geometrically isomorphic to an Artin–Schreier sheaf, there is (by the Langlands Correspondence, due to Lafforgue in this generality) an automorphic representation $\pi$ on some general linear group over the adèle ring of $k(t)$ such that (among other properties) the L-functions of (twists of) $\pi$ coincide (up to normalization) with those of (twists of) the Fourier transform of $\mathcal{F}$. Automorphic methods and results are then available to study the Fourier transform of $\mathcal{F}$.

If $G$ is a commutative algebraic group which is different from $\mathbb{G}_a$, are there objects of a similar nature as automorphic forms and representations that would “correspond” to the arithmetic Fourier transform of suitable perverse sheaves on $G$? Such objects would presumably have some kind of L-function, which would coincide with the $\hat{L}$-function that we have defined. In particular, is there such a theory for $\mathbb{G}_m$?
APPENDIX A

Survey of perverse sheaves

In this appendix, we summarize the basic definitions and facts about \(\ell\)-adic perverse sheaves. The fundamental reference for this material is the work of Beilinson, Bernstein, Deligne and Gabber [6]. Other useful summaries of perverse sheaves are provided by Katz in [63, §2.1 to 2.3] and in [66, §1.1, 1.2, 1.5]. For basic material on trace functions in this context, see also [87, §1.1].

A.1. Complexes of \(\ell\)-adic sheaves

In this appendix, we work over a field \(k\) of characteristic \(p\) and fix a prime \(\ell \neq p\). For \(X\) a separated scheme of finite type over \(k\), one can define the triangulated category of complexes of \(\ell\)-adic sheaves \(D^b_{\text{c}}(X) = D^b_{\text{c}}(X, \mathbb{Q}_\ell)\).

For \(M \in D^b_{\text{c}}(X)\), we write \(H^n(M)\) for the \(n\)-th cohomology sheaf of \(M\), which is an \(\ell\)-adic constructible sheaf. We denote by \(\tau \leq n\) and \(\tau \geq n\) the truncation functors; for every object \(M\), we have canonical maps \(\tau \leq n(M) \to M\) and \(M \to \tau \geq n(M)\). The composite functor \(\tau \geq 0 \circ \tau \leq 0\) is canonically isomorphic to \(M \mapsto H^0(M)\).

For varying \(X\), the categories \(D^b_{\text{c}}(X)\) satisfy all the properties of Grothendieck’s formalism of the six functors (see [27, 1.12] or [6, 2.2.18] in the case when \(k\) is finite or algebraically closed, which suffices for this book).

More precisely, \(D^b_{\text{c}}(X)\) is endowed with two bifunctors \((M, N) \mapsto \text{RHom}(M, N), (M, N) \mapsto M \otimes N\) from \(D^b_{\text{c}}(X) \times D^b_{\text{c}}(X)\) to \(D^b_{\text{c}}(X)\), and for a morphism \(f : X \to Y\) of finite type, we have functors \(M \mapsto Rf_*M\) \(M \mapsto Rf!M\) from \(D^b_{\text{c}}(X)\) to \(D^b_{\text{c}}(Y)\), and functors \(M \mapsto f^*M\) \(M \mapsto f^!M\) from \(D^b_{\text{c}}(Y)\) to \(D^b_{\text{c}}(X)\). These functors satisfy the usual compatibilities and adjunctions.

The dualizing complex for \(X\) is defined to be \(f^!\mathcal{O}_\ell\), where \(f : X \to \text{Spec}(k)\) is the structural morphism, and the Verdier dual of \(M \in D^b_{\text{c}}(X)\) is \(D(M) = \text{RHom}(M, f^!\mathcal{O}_\ell)\). When \(X\) is smooth of pure dimension \(d\), the equality

\[
(A.1) \quad f^!\mathcal{O}_\ell = \mathcal{O}_\ell(d)[2d]
\]

holds.

Let \(s : X \to \text{Spec}(k)\) be the structure morphism. For any object \(M\) of \(D^b_{\text{c}}(X)\) and \(i \in \mathbb{Z}\), the \(i\)-th cohomology group of \(X\) with coefficients in \(M\) (resp. cohomology group with compact support of \(X\) with coefficients in \(M\)) is given by

\[
H^i(X, M) = \mathcal{H}^i(s_*M), \quad H^i(X, M) = \mathcal{H}^i(s^!M)
\]

(identifyng \(\ell\)-adic sheaves on \(\text{Spec}(k)\) with \(\mathcal{O}_\ell\)-vector spaces).

171
When $X$ is a smooth curve, two other important results are used in this book, and will be surveyed in Appendix C (the Euler–Poincaré characteristic formula and Laumon’s product formula for epsilon factors).

A.2. Perverse sheaves

Definition A.1. A complex $M \in \mathcal{D}_c^b(X)$ is said to be semiperverse if its cohomology sheaves satisfy
\[ \dim \text{supp}(\mathcal{H}^i(M)) \leq -i \text{ for every } i \in \mathbb{Z}, \]
and $M$ is said to be perverse if both $M$ and $D(M)$ are semiperverse (see [6, (4.0.1)']).

We denote by $\mathbf{Perv}(X)$ the full subcategory of perverse sheaves in $\mathcal{D}_c^b(X)$, by $\mathcal{P}^\leq_0(X)$ the full subcategory of semiperverse sheaves, and by $\mathcal{P}^{\geq_0}(X)$ the full subcategory of objects $M$ such that $D(M)$ is semiperverse.

Theorem A.2. The data of $\mathcal{P}^{\leq_0}(X)$ and $\mathcal{P}^{\geq_0}(X)$ give rise to a $t$-structure on $\mathcal{D}_c^b(X)$, whose heart $\mathbf{Perv}(X) = \mathcal{P}^{\leq_0}(X) \cap \mathcal{P}^{\geq_0}(X)$ is an abelian category.

Example A.3. Suppose that $X$ is smooth of pure dimension $d$, and let $\mathcal{F}$ be a lisse $\ell$-adic sheaf on $X$. Then the complex $\mathcal{F}[d]$ (i.e., the sheaf $\mathcal{F}$ put in degree $-d$) is a perverse sheaf.

Indeed, $\mathcal{F}[d]$ is clearly semiperverse and by (A.1), we see that $D(\mathcal{F}[d]) = \mathcal{F}^\vee[d]$, where $\mathcal{F}^\vee$ is the dual lisse sheaf of $\mathcal{F}$, so the dual of $\mathcal{F}[d]$ is also semiperverse.

If $M$ is a perverse sheaf with support $Y \subset X$, then there exists an open dense subset of $Y$ such that the restriction of $M$ to $Y$ is lisse, i.e., all of the cohomology sheaves of $M|_Y$ are lisse sheaves. We then say that $M$ is lisse on $U$.

One also defines $\mathcal{P}^{\leq_n}(X) = \mathcal{P}^{\leq_0}(X)[n]$ and $\mathcal{P}^{\geq_n}(X) = \mathcal{P}^{\geq_0}(X)[n]$.

The inclusion functors $\mathcal{P}^{\leq_n}(X) \subset \mathcal{D}_c^b(X)$ and $\mathcal{P}^{\geq_n}(X) \subset \mathcal{D}_c^b(X)$ admit right and left adjoints, called the perverse truncation functors, which are denoted
\[ p_{\tau}^{\leq_n} : \mathcal{D}_c^b(X) \to \mathcal{P}^{\leq_n}(X) \quad \text{and} \quad p_{\tau}^{\geq_n} : \mathcal{D}_c^b(X) \to \mathcal{P}^{\geq_n}(X). \]

Definition A.4. The $n$-th perverse cohomology sheaf of a complex $M \in \mathcal{D}_c^b(X)$ is the perverse sheaf
\[ p_{\mathcal{H}}^n(M) = \tau^{\leq_0-\tau^{\geq_0}}(M[n]) \in \mathbf{Perv}(X). \]

Given a distinguished triangle $M \to N \to L \to$ in $\mathcal{D}_c^b(X)$, we have a long exact sequence (A.2)
\[ \cdots \to p_{\mathcal{H}}^i(M) \to p_{\mathcal{H}}^i(N) \to p_{\mathcal{H}}^i(L) \to p_{\mathcal{H}}^{i-1}(M) \to \cdots \]
of perverse cohomology sheaves.

Let $M$ be a perverse sheaf on $X$. From general principles, there are convergent spectral sequences
(A.3) \[ E_2^{p,q} = H^p(X, p_{\mathcal{H}}^q(M)) \Rightarrow H^{p+q}(X, M), \quad E_2^{p,q} = H^p_c(X, p_{\mathcal{H}}^q(M)) \Rightarrow H^{p+q}_c(X, M), \]
which are called the perverse spectral sequences.

As with the standard $t$-structure, perverse cohomology sheaves give a criterion to check whether a complex is semiperverse.

Lemma A.5. A complex $M \in \mathcal{D}_c^b(X)$ is semiperverse if and only if $p_{\mathcal{H}}^i(M) = 0$ for all integers $i \geq 1$.

See [6, Prop. 1.3.7].
**Definition A.6.** A functor from $D^b_c(X)$ to $D^b_c(Y)$ is said to be *left* $t$*-exact* (resp. *right* $t$*-exact*) if it sends $p^D_{\geq 0}(X)$ to $p^D_{\geq 0}(Y)$ (resp. $p^D_{\leq 0}(X)$ to $p^D_{\leq 0}(Y)$). It is said to be *$t$*-exact* if it is both left and right $t$-exact, *i.e.* if it preserves perverse sheaves.

The following important result is a direct consequence of Artin’s cohomological vanishing theorem (see [6, Th. 4.1.1]).

**Theorem A.7.** Let $f: X \to Y$ be an affine morphism, then $Rf_*$ is *right* $t$*-exact* and $Rf!$ is *left* $t$*-exact*.

Since a closed immersion $i$ is affine and proper (so that $Ri_* = i!$), we obtain as corollary:

**Corollary A.8.** If $i$ is a closed immersion, then $i!$ is *$t$*-exact.

More generally (see [6, Cor. 4.1.3]), the functors $f!$ and $f*$ are *$t$*-exact if $f$ is quasi-finite and affine.

A central result is the construction of the intermediate extension, see [6, Cor. 1.4.25].

**Proposition A.9.** Let $j: U \to X$ be a locally closed immersion. Let $M$ be a perverse sheaf on $U$, then there exists a unique perverse sheaf $j!^*(M)$ on $X$, called the *middle extension* or *intermediate extension* of $M$, such that

- The equality $j^* j!^*(M) = M$ holds;
- The perverse sheaf $j!^*(M)$ is supported on the closure $\overline{U}$ of $U$;
- The perverse sheaf $j!^*(M)$ has no subobject and no quotient supported on $U$. 

The most important example of this construction is when $j: U \to X$ is a dense open immersion, with $U$ smooth of pure dimension $d$, and $M = \mathcal{F}[d]$ for a lisse sheaf $\mathcal{F}$. Note that the uniqueness implies that $D(j!^* \mathcal{F}[d]) = j!^* \mathcal{F}(d)[d]$. When $\mathcal{F} = \mathbb{Q}_l$ is the constant sheaf on $U$, then $j!^* \mathbb{Q}_l[d]$ is called the *intersection complex* of $X$.

**Example A.10.** Let $X$ be a curve, $U$ a dense open subset of $X$ contained in the smooth locus of $X$ and $\mathcal{F}$ a lisse sheaf on $U$. Then $j!^* \mathcal{F}[1] = R^0 j!^* \mathcal{F}[1]$, where $j: U \to X$ is the open immersion.

The fundamental result concerning the category of perverse sheaves is the following theorem [6, Th. 4.3.1].

**Theorem A.11.** The category $\text{Perv}(X)$ is artinian and noetherian. Its simple objects are of the form $j!^* \mathcal{F}[d]$ where $j: U \to X$ is a locally closed immersion with $U$ smooth irreducible of dimension $d$ and $\mathcal{F}$ is an irreducible lisse sheaf on $U$.

**Example A.12.** Let $X$ be a smooth and geometrically connected curve. Following Katz [62, §7.3], a constructible sheaf $\mathcal{F}$ on $X$ is called a *middle extension sheaf* if, for any dense open set $U$ of $X$ such that $\mathcal{F}$ is lisse on $U$, with open immersion $j: U \to X$, the canonical morphism $\mathcal{F} \to j_* j^* \mathcal{F}$ is an isomorphism.

There is a one-to-one correspondance between middle extension sheaves and simple perverse sheaves on $X$ with support equal to $X$; for a middle extension sheaf $\mathcal{F}$, the corresponding simple perverse sheaf is $\mathcal{F}[1]$. Conversely, for a simple perverse sheaf $M$ with support equal to $X$, of the form $j!^* \mathcal{F}[1]$ as in the theorem, we associate the middle extension sheaf $j_* \mathcal{F}$.

For simple perverse sheaves, the bounds on the dimension of the support of the cohomology sheaves has an “automatic improvement” from the bound given by the semi-perversity, except for $\mathcal{H}^{\geq 0}$. 

173
Proposition A.13. Let $M$ be a simple perverse sheaf on $X$ which is not punctual, and with support equal to $X$. Then for any $i \neq -\dim(X)$, we have

$$\dim \text{supp}(\mathcal{H}^i(M)) \leq -i - 1.$$  

Proof. This results from the classification of simple perverse sheaves and from the general description of the intermediate extension functor in [6, Prop. 2.1.11]. □

Example A.14. In the case of a curve, this property can be seen from Example A.10, since in that case any simple perverse sheaf which is not punctual is supported on a dense open subset.

We thank S. Morel for communicating us a proof of the following lemma (see also [66, Sublemma 1.10.5]).

Lemma A.15. Let $k$ be an algebraically closed field. Let $X$ be an irreducible projective variety of dimension $d$ over $k$, and let $M$ be a simple perverse sheaf on $X$ such that $H^{-d}(X, M)$ is non-zero. Then there exists an open immersion $j: U \hookrightarrow X$ such that $M = j_!\mathbb{Q}_\ell[\ell]$.

Proof. By the classification of simple perverse sheaves in Theorem A.11, there exists an open immersion $j: U \hookrightarrow X$ and a simple lisse sheaf $F$ on $U$ such that $M = j_!F[\ell]$. Since $X$ has dimension $d$, the cohomology $H^i(X, M)$ vanishes for $i \notin [-d, d]$ by [6, 4.2.4]. Besides, the formula for intermediate extensions from [6, 2.1.11] implies the vanishing $H^i(M) = 0$ for $i < -d$. From the spectral sequence

$$E_2^{pq} = H^p(X, \mathcal{H}^q(M)) \Rightarrow H^{p+q}(X, M),$$

we then get an isomorphism $H^{-d}(X, M) \simeq H^0(X, \mathcal{H}^{-d}(M))$. The non-vanishing of this cohomology group implies that $\mathcal{H}^{-d}(M)$ has a global section. Hence, $F$ has a global section and is therefore trivial. □

A.3. Weights

In this section we assume that $k$ is a finite field of characteristic $p$, and denote by $\bar{k}$ an algebraic closure. We also fix an isomorphism $\iota: \bar{\mathbb{Q}_\ell} \to \mathbb{C}$.

Let $q$ be a prime power and let $w \in \mathbb{Z}$ be an integer. A element $x \in \bar{\mathbb{Q}_\ell}$ is said to be a $q$-Weil number of weight $w$ if it is algebraic over $\mathbb{Q}$, and if all the complex conjugates of $\iota(x)$ are complex numbers with modulus $q^w/2$.

Let $X$ be a separated scheme of finite type over $k$ and $\mathcal{F}$ a $\bar{\mathbb{Q}_\ell}$-sheaf on $X$. Let $x$ be a closed point of $X$, with residue field $k(x)$. Viewing $k(x)$ as a subfield of the fixed algebraic closure $\bar{k}$ of $k$ defines a geometric point $\bar{x}: \text{Spec}(\bar{k}) \to X$ supported at $x$. The geometric Frobenius automorphism, inverse of $y \mapsto y^{k(x)}$ in $\text{Gal}(\bar{k}/k)$, acts on the stalk $\mathcal{F}_{\bar{x}}$ of $\mathcal{F}$ at $\bar{x}$. We denote by $\text{Fr}_x$ this endomorphism of $\mathcal{F}_{\bar{x}}$.

Definition A.16 ([27, 1.2], [6, 5.1.5]). Let $X$ be a separated scheme of finite type over $k$, $\mathcal{F}$ a $\bar{\mathbb{Q}_\ell}$-sheaf on $X$, and $M$ an object of $D^b_c(X)$.

1. The sheaf $\mathcal{F}$ is punctually pure of weight $w$ if for every $x \in |X|$, the eigenvalues of $\text{Fr}_x$ are $|k(x)|$-Weil numbers of weight $w$.

2. The sheaf $\mathcal{F}$ is mixed if it admits a finite filtration with successive quotients that are punctually pure. It is mixed of weights $\leq w$ (resp. of weights $\geq w$) if all the non-zero successive quotients are punctually pure of some weight $\leq w$ (resp. $\geq w$).
(3) The complex $M$ is **mixed** if all its cohomology sheaves are mixed. It is **mixed of weights** \( \leq w \) if for every \( i \in \mathbb{Z} \), the sheaf \( \mathcal{H}^i(M) \) is mixed of weights \( \leq w + i \). It is **mixed of weights** \( \geq w \) if its Verdier dual \( D(M) \) is mixed of weights \( \leq w \).

(4) The complex $M$ is **pure of weight** $w$ if it is mixed of weights \( \leq w \) and \( \geq w \).

**Remark A.17.** Deligne also defines \( \iota \)-weights and \( \iota \)-pure or mixed sheaves and complexes for any fixed isomorphism \( \iota \); the notion above means that the objects are \( \iota \)-pure for all \( \iota \) (see [27, 1.2.6]).

We write \( D_{\leq w}(X) \) and \( D_{\geq w}(X) \) for the full subcategories of \( D^b_c(X) \) of objects mixed of weights \( \leq w \) and \( \geq w \). Thanks to the shift in the definition, one has in particular \( D_{\leq w}[1] = D_{\leq w+1} \).

**Example A.18.** (1) Suppose that $X$ is smooth of pure dimension $d$, and that $M \in D^b_c(X)$ is such that all its cohomology sheaves are lisse on $X$. Then $M$ is pure of weight $w$ if and only if each sheaf $H^i(M)$ is punctually pure of weight $w + i$.

(2) The characterization of (1) does not apply in general. For instance, let $X = \mathbb{A}^1$ be the affine line, and $j: \mathbb{G}_m \to X$ the open immersion. Let $M = (j_*\mathcal{K}_2)[1](1/2)$ be the Kloosterman sheaf of rank 2 shifted to be in degree $-1$ and Tate-twisted to be of weight 0 (see (B.2)). Then $M$ is pure of weight 0. However, the cohomology sheaf $H^{-1}(M) = j_*\mathcal{K}_2(1/2)$ is not punctually pure of weight $-1$: indeed, the stalk of this sheaf at 0 has rank 1 with a Frobenius eigenvalue of weight $-2$.

Deligne’s main theorem in [27, 3.3.1, 6.2.3], which directly implies the most general form of the Riemann Hypothesis over finite fields, is the following:

**Theorem A.19 (Deligne).** Let $f: X \to Y$ be a separated morphism of schemes of finite type over $k$. Then the functor $Rf_!$ sends $D_{\leq w}(X)$ to $D_{\leq w}(X)$.

Using duality, one gets the following list of compatibilities of the different functors on $D^b_c(X)$ (see [6, 5.1.14]):

1. \( Rf_! \) and \( f^* \) preserve $D_{\leq w}$;
2. \( Rf_* \) and \( f! \) preserve $D_{\geq w}$;
3. \( \otimes \) sends $D_{\leq w} \times D_{\leq w'}$ to $D_{\leq w+w'}$;
4. \( R\text{Hom} \) sends $D_{\geq w} \times D_{\geq w'}$ to $D_{\geq w+w'}$;
5. \( D \) exchanges $D_{\leq w}$ and $D_{\geq w}$.

**A.4. Trace functions**

We continue with the notation of the previous section, so that $X$ is an algebraic variety over a finite field $k$.

Let $M$ be a complex in $D^b_c(X)$. For any integer $n \geq 1$ and $x \in X(k_n)$, the stalk $M_{\bar{x}}$ of $M$ at a geometric point $\bar{x}$ above $x$ is a complex of finite-dimensional $\mathbb{Q}_l$-vector spaces, with only finitely many non-zero cohomology spaces. The geometric Frobenius $\text{Fr}_{k_n}$ of $k_n$ (the inverse of the automorphism $a \mapsto a^{[k_n]}$ of $k_n$) acts on $M_{\bar{x}}$, and this action is independent of the choice of $\bar{x}$ up to conjugacy. We denote

$$t_M(x; k_n) = \sum_{i \in \mathbb{Z}} (-1)^i \text{Tr}(\text{Fr}_{k_n} | \mathcal{H}^i(X)_{\bar{x}}),$$

which is also independent of $\bar{x}$ above $x$. 

175
Whenever we have fixed the isomorphism $\iota_0: \overline{Q}_\ell \to C$ (as in the whole of the main text, see Section 3), we will view the trace function as a function $X(k_n) \to C$ whenever convenient.

**Definition A.20.** The trace function $t_M$ of $M$ is the data of the whole family of functions $(t_M(; k_n))_{n \geq 1}$.

**Remark A.21.** We will sometimes write simply $t_M(x)$ for $t_M(x; k_n)$, when $x \in X(k)$.

Viewing $X(k_n)$ as a subset of $X(\bar{k})$, we will also sometimes denote the stalk of $M$ simply by $M_x$, instead of introducing explicitly a specific geometric point over $x$.

Let $f: X \to Y$ be a morphism of algebraic varieties over $k$. The following properties holds for objects $M_1$ and $M$ of $D^b_c(X)$ and $N$ of $D^b_c(Y)$:

- $t_{\overline{Q}_\ell} = 1$ (\overline{Q}_\ell in degree 0)
- $t_{M[k]} = (-1)^k t_M$, $t_{M(w)} = q^{-w/2} t_M$
- $t_{M_2} = t_{M_1} + t_{M_3}$ for any distinguished triangle $M_1 \to M_2 \to M_3 \to$
- $t_{M_1 \oplus M_2} = t_{M_1} t_{M_2}$
- $t_{f^*N} = t_N \circ f$, i.e. $t_{f^*N}(x; k_n) = t_N(f(x); k_n)$ for all $n \geq 1$ and $x \in X(k_n)$
- $t_{Rf_*M}(y; k_n) = \sum_{x \in X(k_n), f(x) = y} t_M(x; k_n)$

The last of these properties is a form of the Grothendieck–Lefschetz trace formula (see [1, Exp. III, §4]). Applied to a complex $M$ and to the structure morphism $X \to \text{Spec}(k)$, it takes the customary form

(A.4) \[ \sum_{x \in X(k_n)} t_M(x; k_n) = \sum_{i \in \mathbb{Z}} (-1)^i \text{Tr}(Fr_{k_n} | H^i_c(X_{\bar{k}}, M)). \]

Suppose that $M$ is a semisimple perverse sheaf which is pure of weight 0. Then by a result of Gabber (see [100, proof of Prop. 6.39]), the equality

(A.5) \[ t_{D(M)}(x; k_n) = \overline{t_M(x; k_n)} \]

holds for all $n \geq 1$ and $x \in X(k_n)$.

We also recall a useful injectivity statement:

**Proposition A.22.** Let $M_1$ and $M_2$ be objects of $D^b_c(X)$. The trace functions of $M_1$ and $M_2$ coincide, in the sense that

$t_{M_1}(x; k_n) = t_{M_2}(x; k_n)$

for all $n \geq 1$ and all $x \in X(k_n)$, if and only if the classes of $M_1$ and $M_2$ in the Grothendieck group $K(X)$ are equal. In particular, if $M$ and $N$ are semisimple perverse sheaves, then $M$ and $N$ are isomorphic.

Moreover, the classes of simple perverse sheaves form a basis of the $\mathbb{Z}$-module $K(X)$.

This is proved in [87, Th. 1.1.2].
The arithmetic Mellin transform over finite fields

We summarize here the most important results of Katz [68] concerning the arithmetic Mellin transform on $G_m$. These results are used in various places in the book.

B.1. The category $\mathcal{P}$

Let $k$ be a finite field with algebraic closure $\overline{k}$ and with finite extensions $k_n/k$ for $n \geq 1$.

Katz defines a category $\mathcal{P}$ as the full subcategory of the category of perverse sheaves on $G_m$ over $\overline{k}$ whose objects are perverse sheaves $N$ such that, for any perverse sheaf $M$ on $G_m$, the objects $M \ast_! N$ and $M \ast_* N$ are both perverse (see [68, Ch.2] and [63, 2.6.2]). Katz proved that a perverse sheaf $N$ is an object of $\mathcal{P}$ if and only if it admits no shifted Kummer sheaf $L_{\chi}[1]$ as either subobject or quotient (this follows, e.g, from the combination of [63, Lemma 2.6.13, Lemma 2.6.14, Cor. 2.6.15]).

The category $\mathcal{P}_{\text{ari}}$ is defined as the full subcategory of perverse sheaves on $G_m$ over $k$ whose objects are those perverse sheaves $N$ such that the base change of $N$ to $\overline{k}$ is an object of $\mathcal{P}$ ([68, Ch.4]).

Using the correct notion of exactness from the work of Gabber and Loeser, the categories $\mathcal{P}_{\text{ari}}$ and $\mathcal{P}$ are neutral tannakian categories with the middle convolution

$$M \ast_{\text{int}} N = \text{Im}(M \ast_! N \rightarrow M \ast_* N)$$

as tensor operation (see [46, p.535]).

The tannakian dimension of an object of $\mathcal{P}$ is its Euler–Poincaré characteristic.

B.2. Deligne’s fiber functor and Frobenius conjugacy classes

One remarkable canonical fiber functor on this tannakian category is given by a theorem of Deligne.

**Theorem B.1** (Deligne). Let $k$ be a finite field with algebraic closure $\overline{k}$. Let $j_0: G_m \rightarrow A^1$ be the open immersion. Then the functor

$$\omega_{\text{Del}}: M \mapsto H^0(A^1_{k^\times}, j_0^! M)$$

is a fiber functor on the category $\mathcal{P}$.

This is [68, Th.3.1 and Appendix].

Let $N$ be an object of $\mathcal{P}_{\text{ari}}$ which is arithmetically semisimple and pure of weight 0. Let $G^\text{ari}_N$ be the tannakian group of the tannakian subcategory of $\mathcal{P}_{\text{ari}}$ generated by $N$. Using Deligne’s fiber functor and the tannakian formalism, Katz defines a Frobenius conjugacy $\text{Fr}_{N,k_n}(\chi)$ in $G^\text{ari}_N$ for any $n \geq 1$ and any $\ell$-adic character $\chi$ of $k_n^\times$ by considering the fiber functor $\omega_{\chi}: M \mapsto \omega_{\text{Del}}(M_{\chi})$ (see [68, Ch.5]).
B.3. Finite tannakian groups

Theorem B.2 (Katz). Let $k$ be a finite field with algebraic closure $\bar{k}$. Let $N$ be a perverse sheaf in the category $\mathcal{P}_{ari}$. Assume that $N$ is arithmetically semisimple and pure of weight 0.

1. If every Frobenius conjugacy class of $N$ is quasi-unipotent, then the object $N$ is punctual.
2. If the geometric tannakian group of $N$, i.e., the tannakian group of the tannakian subcategory of $\mathcal{P}$ generated by $N \otimes \bar{k}$, is finite, then the object $N$ is punctual.

These statements are [68, Th 6.2 and Th. 6.4].

B.4. Hypergeometric sheaves

Katz has also classified the perverse sheaves on $\mathbb{G}_m$ with tannakian dimension 0 and 1. Indeed, since the tannakian dimension is equal to the Euler–Poincaré characteristic in this case, the question is to classify simple perverse sheaves $M$ on $\mathbb{G}_m$ with $\chi(M) = 0$ or 1.

For Euler–Poincaré characteristic zero, we have:

Proposition B.3. Let $k$ be an algebraically closed field of characteristic $p > 0$ with $p \neq \ell$. Let $M$ be a simple perverse sheaf on $\mathbb{G}_m$ with $\chi(\mathbb{G}_m, M) = 0$. Then there exists a tame character $\chi$ of $\mathbb{G}_m$ such that $M$ is isomorphic to $L^1(\chi)$.

This is [62, Prop. 8.5.2].

For Euler–Poincaré characteristic 1, Katz had shown that these are exactly the hypergeometric sheaves on $\mathbb{G}_m$, defined in [62, 8.2, 8.3].

We recall the definition and notation for hypergeometric sheaves. Let $k$ be a field of positive characteristic. Fix a pair $(m,n)$ of non-negative integers and a non-trivial $\ell$-adic additive character $\psi$ of a finite subfield of $k$. Denote by $j: \mathbb{G}_m \to \mathbb{A}_1$ the open immersion. Let $\chi = (\chi_1, \ldots, \chi_n)$, $\varrho = (\varrho_1, \ldots, \varrho_m)$ be two tuples of tame $\ell$-adic continuous characters $\pi_t(\mathbb{G}_m) \to \mathbb{Q}_\ell^\times$. Denote by $\bar{\psi}$ the inverse of $\psi$ and write
$$\bar{\chi} = (\chi_1^{-1}, \ldots, \chi_n^{-1}), \quad \bar{\varrho} = (\varrho_1^{-1}, \ldots, \varrho_m^{-1}).$$

The hypergeometric complex $\text{Hyp}(!, \psi, \chi; \varrho)$ in $D^b_c(\mathbb{G}_m)$ is then defined inductively as follows:

1. If $(m, n) = (0, 0)$ then $\text{Hyp}(!, \psi, \emptyset; \emptyset)$ is the skyscraper sheaf supported at 1.
2. If $(m, n) = (1, 0)$ then $\text{Hyp}(!, \psi, \chi; \emptyset) = j^*(\mathcal{L}_\psi) \otimes \mathcal{L}_\chi[1]$.
3. If $(m, n) = (0, 1)$ then $\text{Hyp}(!, \psi, \emptyset, \varrho) = \text{inv}^*(j^*(\mathcal{L}_\varrho) \otimes \mathcal{L}_\psi)[1]$.
4. If $(m, n) = (m, 0)$ with $m \geq 2$ then $\text{Hyp}(!, \psi, \chi; \emptyset)$ is the convolution $\text{Hyp}(!, \psi, \chi_1; \emptyset) \ast \cdots \ast \text{Hyp}(!, \psi, \chi_n; \emptyset)$.
5. If $(m, n) = (0, n)$ with $n \geq 2$ then $\text{Hyp}(!, \psi, \emptyset; \varrho)$ is the convolution $\text{Hyp}(!, \psi, \emptyset; \varrho_1) \ast \cdots \ast \text{Hyp}(!, \psi, \emptyset; \varrho_n)$.
6. In the general case, we have $\text{Hyp}(!, \psi, \chi; \varrho) = \text{Hyp}(!, \psi, \chi; \emptyset) \ast \text{Hyp}(!, \psi, \emptyset; \varrho)$.

For $\lambda \in k^\times$, define also
$$\text{Hyp}_\lambda(!, \psi, \chi; \varrho) = [x \mapsto \lambda x]_* \text{Hyp}(!, \psi, \chi; \varrho).$$
It follows from these definitions that the general convolution formula
\[ \text{Hyp}_\lambda((1, \psi, \chi; \rho)) \ast_1 \text{Hyp}_\mu((1, \psi, \chi'; \rho')) = \text{Hyp}_{\lambda\mu}((1, \psi, \chi; \rho, \rho')) \]
holds.

Let \( K \) be an extension of \( k \). We say that a complex \( M \) on \( G_m \) over \( K \) is hypergeometric over \( k \) if there exists \( \lambda \in k^\times \), an additive character \( \psi \), and families of tame multiplicative characters \( \chi \) and \( \rho \) such that \( M \otimes K \) is isomorphic to \( \text{Hyp}_\lambda((1, \psi, \chi; \rho)) \), where the characters involved are defined on \( G_m \) over \( K \) by composition with \( \pi_1^0((G_m)_K) \to \pi_1^0((G_m)_k) \to \overline{\mathbb{Q}}_\ell^\times \).

Before stating the main theorem concerning hypergeometric sheaves, we need a further definition: the tuples \( \chi \) and \( \rho \) are said to be disjoint if \((n, m) \neq (0, 0) \) and \( \chi_i \neq \rho_j \) for all \( i \) and \( j \).

**Theorem B.4 (Katz).** Assume that \( k \) is algebraically closed.

(1) If the tuples \( \chi \) and \( \rho \) are disjoint, then \( \text{Hyp}_\lambda((1, \psi, \chi; \rho)) \) is a simple nonpunctual perverse sheaf of Euler characteristic \( 1 \) on \( G_m \).

(2) Let \( K \) be an extension of \( k \) and \( K \) an algebraic closure of \( K \). Let \( M \) be a simple perverse sheaf \( M \) on \( G_m \) over \( K \) with Euler–Poincaré characteristic equal to 1. Then the base change \( M \otimes K \) of \( M \) to \( K \) is hypergeometric over \( K \), i.e., there exists \( \lambda \in K^\times \), an additive character \( \psi \), and disjoint families of tame multiplicative characters \( \chi \) and \( \rho \) such that \( M \otimes K \) is isomorphic to \( \text{Hyp}_\lambda((1, \psi, \chi; \rho)) \).

(3) Let \( k \) be a finite field and \( K \) an algebraic closure of \( k \). If \( m + n \geq 1 \), then the tannakian group of the hypergeometric object \( \text{Hyp}_\lambda((1, \psi, \chi; \rho)) \) on \( G_m \) over \( K \) is \( GL_1 \).

**Proof.** The first statement follows from \([62, \text{Th. 8.4.2}]\), and the third is explained, e.g., in \([68, \text{proof of Cor. 6.3}]\).

The second statement is \([62, \text{Th. 8.5.3}]\) if \( K = \overline{K} = k \). Applied to \( K \) instead of an algebraic closure of \( k \), this gives the result except that we only know that \( \lambda \in \overline{K}^\times \). We need to check that in fact \( \lambda \in K^\times \). To do this, we check the steps of the proof of loc. cit., which is easily seen to provide this extra information.

Indeed, roughly speaking, the strategy of the proof is to say that \( M \) is of type \((n, m)\), where \( n \) (resp. \( m \)) is the dimension of the tame part of \( M \) at \( 0 \) (resp. \( \infty \)), then to reduce by induction to the case \( m > n \), then to \( n = 0 \) and finally to the case \( m = n = 0 \).

Each of these reduction steps follows a similar pattern. First, up to tensoring \( M \) by \( \mathcal{L}_\Lambda \) for some tame continuous character \( \Lambda \) of \( \pi_1^0((G_m)_K) \), one can assume that the trivial character occurs in the local monodromy at \( 0 \). From Kummer theory, we have an isomorphism \( \pi_1^0((G_m)_K) \simeq \hat{\mathbb{Z}}(1)_{\mu'} \); since \( M \) is defined over \( K(\eta) \), the character \( \Lambda \) must be of finite order and a character of \( k^\times \). All the characters \( \chi \) and \( \rho \) appear as such \( \Lambda \).

After this tensoring step, one considers the Fourier transform \( \text{FT}_\psi(j_* M) \), and one checks that it is of type \((n, m - 1)\), and is still a geometrically simple perverse sheaf of Euler characteristic \( 1 \).

At the end of the induction, one is left either with a skyscraper sheaf, which must be supported on some \( \lambda \in K^\times \) since \( M \) is geometrically simple, or with a perverse sheaf that is geometrically isomorphic to \( \mathcal{L}_{\chi(\lambda \mu)} \) for some \( \lambda \in K^\times \), and since this sheaf is defined over \( K \), we must have \( \lambda \in K \), as desired.

**Remark B.5.** (1) In \([62, \text{Ch. 8}]\), Katz has also determined the geometric monodromy group of almost all hypergeometric sheaves. We observe in passing that this computation has recently been used by Fresán and Jossen \([40]\) to construct examples of \( E \)-functions that are not related to hypergeometric functions, answering a question raised by Siegel in his fundamental paper \([108]\).
(2) It is not difficult to deduce from this result that the set of isomorphism classes of objects of \( \mathbf{P}_{\text{int}}(G_m) \) with tannakian dimension one (i.e., objects \( M \) with \( \chi(M) = 1 \)) forms an abelian group \( H_{\text{int}}(G_m) \), with product given by the internal convolution, which is isomorphic to 
\[
\bar{k}^\times \times \mathbb{Z}_{\pi}^{\mathcal{I}}(G_m,k).
\]

An isomomorphism \( \Phi \) between these groups is determined as follows: given \( \lambda \in \bar{k}^\times \) and a function \( f \in \mathbb{Z}_{\pi}^{\mathcal{I}}(G_k,\bar{k}) \), let \( \chi \) be the tuple whose distinct elements are the characters \( \chi \) such that \( f(\chi) \geq 1 \), each repeated with multiplicity \( f(\chi) \), and let \( \varrho \) be the tuple whose distinct elements are the characters \( \chi \) such that \( f(\chi) \leq -1 \), each repeated with multiplicity \( f(\chi) \). Then one has
\[
\Phi(\lambda, f) = \text{Hyp}_{\lambda}(!, \psi, \chi; \varrho).
\]

Conversely, the function \( f \) can be recovered from an element \( M \) of \( H_{\text{int}}(G_m) \) by looking at the tame characters appearing in the local monodromy at 0 and \( \infty \), and their multiplicities.

This result is a special case of a general result of Gabber and Loeser, valid for any torus (see [46, Th. 8.6.1]).

Let now \( k \) be a finite field, with \( \psi \) a non-trivial additive character of \( k \). Let \( \lambda \in k^\times \) and let
\[ M = \text{Hyp}_{\lambda}(!, \psi, \chi; \varrho) \]
for tuples \( \chi \) and \( \varrho \) of tame characters associated to multiplicative characters \( k^\times \rightarrow \mathbb{Q}_\ell^\times \) (denoted in the same manner). The trace function of \( M \) is then given by
\[
t_M(x; k) = (-1)^{n-m} \sum_{(x_i)\in(k^\times)^m, (y_j)\in(k^\times)^n} \psi\left(\sum_{i=1}^m x_i - \sum_{j=1}^n y_j\right) \prod_{i=1}^m \chi_i(x_i) \prod_{j=1}^n \varrho_j(y_j),
\]
with the obvious analogue for finite extensions of \( k \). For a multiplicative character \( \chi: k^\times \rightarrow \mathbb{Q}_\ell^\times \), let
\[
\tau(\psi, \chi) = \sum_{x \in k^\times} \psi(x) \chi(x)
\]
denote the Gauss sums over \( k \). Then the arithmetic Mellin transform of the complex \( M \) is
\[
(B.1) \quad \sum_{x \in k^\times} \chi(x)t_M(x; k) = \chi(\lambda) \prod_{i=1}^m \tau(\psi, \chi_i) \prod_{j=1}^n \tau(\bar{\psi}, \bar{\chi}\varrho_j)
\]
for \( \chi: k^\times \rightarrow \mathbb{Q}_\ell^\times \), i.e., a monomial in Gauss sums (see [62, (8.2.7), (8.2.8)]).

In particular, if \( m \geq 1 \) and \( \chi_i = 1 \) for all \( i \), and if \( \varrho \) is empty, we obtain the hyper-Kloosterman sums
\[
\text{Kl}_m(x; k) = (-1)^m \sum_{x_1, \ldots, x_m \in k^\times, x_1 \cdots x_m = \lambda^{-1} x} \psi(x_1 + \cdots + x_n).
\]

The corresponding hypergeometric sheaf
\[
(B.2) \quad \mathcal{H}^\ell_{m, \psi} = \text{Hyp}(!, \psi, (1, \ldots, 1); \emptyset)
\]
is also called a Kloosterman sheaf.
APPENDIX C

The product formula for epsilon factors

We recall in this Appendix the formula of Laumon [87] for the epsilon factor of an object of $D^b_c(X)$ on a curve $X$, and recall the main parts of the formalism of local epsilon factors. We also include the general Euler–Poincaré characteristic formula.

C.1. The product formula

The results in this section are quoted directly from [87, §3].

Let $k$ be a finite field of characteristic $p$, with $k_n/k$ the extension of $k$ of degree $n$ in an algebraic closure $ar{k}$ of $k$.

Let $X$ be a smooth projective curve over $k$. We denote by $[X]$ the set of closed points of $X$. For a complex $M$ in $D^b_c(X)$, the $L$-function of $M$ is defined by the product

$$L(M, T) = \prod_{x \in [X]} \det(1 - T^{\deg(x)} Fr_{k^{\deg(x)}} | M_x)^{-1}.$$ 

It satisfies the relation

$$L(M, T) = \det(1 - T Fr_k | H^*(X_{\bar{k}}, M))^{-1}$$

and the functional equation

$$L(M, T) = \varepsilon(M) T^{a(M)} L(D(M), T^{-1}),$$

where

$$a(M) = -\chi(X_{\bar{k}}, M),$$

$$\varepsilon(M) = \det(- Fr_k | H^*(X_{\bar{k}}, M))^{-1}.$$ 

Laumon’s product formula, which had been conjectured by Deligne, is an expression for $\varepsilon(M)$ in terms of local epsilon factors.

Consider a fixed non-trivial $\ell$-adic additive character $\psi$ of $\mathbb{F}_p$, and denote $\psi_k = \psi \circ \text{Tr}_{k/\mathbb{F}_p}$. Furthermore, consider a fixed non-zero meromorphic 1-form $\omega$ on $X$.

**Theorem C.1** (Laumon). Suppose that $X$ is connected. Let $g$ be the common genus of all the connected components of $X_{\bar{k}}$, and $n \geq 1$ the number of these connected components.

Let $M$ be an object of $D^b_c(X)$ of generic rank $r(M)$. There exist specific local constants $\varepsilon_x(M)$, depending on the choice of $\omega$, such that

$$(C.1) \quad \varepsilon(M) = |k|^c \prod_{x \in [X]} \varepsilon_x(M)$$

where $c = n(1 - g)r(M)$.

This is [87, Th. 3.2.1.1], defining (in the notation of loc. cit.) the local factors by

$$(C.2) \quad \varepsilon_x(M) = \varepsilon(X(x), M|X(x), \omega|X(x)).$$
C.2. Local epsilon factors

We summarize here the basic identities and formal properties of the local epsilon factors $\varepsilon_x(M)$ in Laumon’s Theorem C.1. The existence and uniqueness of these local factors, subject to certain conditions, are given precisely by Laumon in [87, Th 3.1.5.4]; they were define earlier by Deligne [25].

The local epsilon factors are attached to a triple $(T, M, \omega)$, where $T$ is a strictly henselian local ring of equal characteristic with residue field containing $k$, $M$ is an object of $\text{D}^b_c(T)$ and $\omega$ is a non-zero meromorphic 1-form on $T$.

The notation $\varepsilon(X(x), M|X(x), \omega|X(x))$ in (C.2) refers to these factors with the subscript $(x)$ referring to strict localization at $x$.

We require further the local exponents $a(T, M, \omega)$ and $a(T, M)$. These are defined in [87, (3.1.5.1), (3.1.5.2)]. In order to recall the definition, we use some following additional notation (see [87, 3.1.5]):

1. We denote by $v$ the valuation of $T$, extended to 1-forms by $v(ab) = v(a)$ if $v(b) = 1$.
2. We denote by $t$ the closed point of $T$ and by $\eta$ the generic point.
3. We denote by $\bar{t}$ (resp. $\bar{\eta}$) a geometric generic point of $T$ above $t$ (resp. above $\eta$).
4. We denote by $k_t$ the residue field of $T$ at $t$.
5. For an object $M$ of $\text{D}^b_c(T)$, we denote by $r(M|\bar{\eta})$ (resp. $r(M|\bar{t})$) the generic rank of $M$ (resp. the rank of the stalk at the closed point) and by $s(M|\bar{\eta})$ the Swan conductor; all of these are defined for an étale sheaf first and extended by additivity, see [87, §2.2.1].

With these notation, the local conductor exponents are defined by the formulas

\begin{align*}
a(T, M, \omega) &= a(T, M) + r(M|\bar{\eta})v(\omega) \\
a(T, M) &= r(M|\bar{\eta}) + s(M|\bar{\eta}) - r(M|\bar{t}),
\end{align*}

In the global case, we will denote

$$a_x(M, \omega) = a(X(x), M|X(x), \omega|X(x)).$$

Furthermore, for a lisse $\mathbb{Q}_\ell$-sheaf $F$ on the generic point $\eta$ of $T$, one defines

\begin{equation}
\varepsilon_0(T, F, \omega) = \varepsilon(T, j_!F, \omega),
\end{equation}

where $j: \{\eta\} \to T$ is the open immersion (see [87, 3.1.5.6, p.187]).

For a short exact sequence $0 \to F' \to F \to F'' \to 0$, we have

\begin{equation}
\varepsilon_0(T, F, \omega) = \varepsilon_0(T, F', \omega)\varepsilon_0(T, F'', \omega).
\end{equation}

The local epsilon factors satisfy (among other things) the following properties, which are used in Chapter 11 in the proof of Proposition 11.11.

1. For any lisse $\mathbb{Q}_\ell$-sheaf $F$ of rank $r$ on $T$, the formula

\begin{equation}
\varepsilon(T, M \otimes F, \omega) = \det(Fr_{\mid F})^{a(T, M, \omega)}\varepsilon(T, M, \omega)^r
\end{equation}

holds, where $Fr$ denotes the geometric Frobenius automorphism at the closed point $t$ of $T$. 

182
(2) For a non-zero rational function \( a \) on \( T \), the formula
\[
\varepsilon(T, M, a\omega) = \chi(a)|k_t|^{r(M)}\varepsilon(T, M, \omega)
\]
holds, where \( \chi \) is the character of the completion of the residue field at the generic point of \( T \) induced by the restriction of the lisse sheaf \( \det(M) \) by local class-field theory, normalized as explained in [87, (3.1.4)].

(3) For a non-trivial multiplicative character \( \chi \) of the residue field \( k_t \) and the corresponding lisse Kummer sheaf \( \mathcal{L}_\chi \) on \( \{ \eta \} \), and for a uniformizer \( \pi \) at \( x \), we have
\[
\varepsilon_0(T, \mathcal{L}_\chi, d\pi) = \chi(-1) \sum_{a \in k_t^\times} \chi(a) \psi_t(a)
\]
where \( \psi_t(a) = \psi \circ \text{Tr}_{k_t/F_p} \).

See, respectively, formula (3.1.5.6), formula (3.1.5.5) and section 3.5.3.1 in [87].

We also have the elementary shift formula
\[
\varepsilon(T, M[1], \omega) = \varepsilon(T, M, \omega)^{-1}.
\]

### C.3. The Euler–Poincaré characteristic formula

We keep the notation of Section C.1. In particular, \( X \) is a smooth projective curve over a finite field \( k \) with algebraic closure \( \bar{k} \). We assume that \( X \) is geometrically connected, and denote by \( g \) the genus of \( X \).

Let \( M \) be a complex in \( D^b_c(X) \). For any point \( x \in X(\bar{k}) \), the Swan conductor \( \text{swan}_x(M) \) is defined by additivity from the case of a \( \mathbb{Q}_\ell \)-sheaf (in which case, it is defined for instance in [87, (2.1.2.5)] or [61, Ch. 1]). Similarly, the drop \( \text{drop}_x(M) \) is defined by additivity from the drop
\[
\text{drop}_x(\mathcal{F}) = \text{rank}(\mathcal{F}) - \dim(\mathcal{F}_x)
\]
of a \( \overline{\mathbb{Q}}_\ell \)-sheaf \( \mathcal{F} \).

**Theorem C.2** (Grothendieck–Ogg–Shafarevich). *Let \( U \subset X \) be an open dense subset. Let \( M \) be a complex in \( D^b_c(U) \), let \( V \) be an open dense subset of \( U \) on which \( M \) is lisse of generic rank \( r(M) \). We have
\[
\chi(X, M) = \chi(U, \overline{\mathbb{Q}_\ell} \cdot r(M)) - \sum_{x \in X(\bar{k})} \text{swan}_x(M) - \sum_{x \in U(\bar{k})} \text{drop}_x(M),
\]
where \( \chi(X, \overline{\mathbb{Q}_\ell}) = (2 - 2g) - |(X - U)| \).*

This statement follows from [87, Th. 2.2.1.2], which corresponds to \( X = U \) (up to changes in notation) by applying this result to \( j_*M \), where \( j: U \to X \) is the open immersion, and using the additivity of the Euler–Poincaré characteristic, in the sense that
\[
\chi(X, j_*M) = \chi(U, M) + \chi((X - U), i^*j_*M)
\]
with \( i \) the closed immersion of \( X - U \) in \( X \).

For the case of a \( \overline{\mathbb{Q}}_\ell \)-sheaf, the statement is also given for instance in [68, Ch. 14].

We consider some special cases that appear in this book.

(1) If \( U = X \) and \( M = \mathcal{F}[1] \) for some \( \overline{\mathbb{Q}}_\ell \)-sheaf of generic rank \( r \) on \( X \), then the formula becomes
\[
\chi(X, M) = (2g - 2)r + \sum_{x \in X(\bar{k})} (\text{swan}_x(\mathcal{F}) + \text{drop}_x(\mathcal{F})).
\]
(2) If $U = \mathbb{G}_m \subset X = \mathbf{P}^1$ and $M = \mathcal{F}[1]$ for some $\mathbb{Q}_{\ell}$-sheaf of generic rank $r$ on $\mathbb{G}_m$, then

\begin{equation}
\chi((\mathbb{G}_m)_k, M) = \mathrm{swan}_0(\mathcal{F}) + \mathrm{swan}_\infty(\mathcal{F}) + \sum_{x \in k^\times} (\mathrm{swan}_x(\mathcal{F}) + \mathrm{drop}_x(\mathcal{F})).
\end{equation}
Deligne’s letter to Kazhdan

We reproduce below the content of Deligne’s letter to Kazhdan, in which the ℓ-adic Fourier transform was defined for the first time (the typography is not faithfully reproduced).

29-11-76

Dear Каждан,

This is perhaps a partial answer to an old letter of yours. I thought to the matter again because of some estimations of trigonometrical sums Hooley asked me about. As I am in a hurry to continue writing up Weil II, I will leave many open ends and soon turn to French.

Theme: many functions correspond to sheaves, and operations on functions to operations on sheaves. What about harmonic analysis on $G_a$?

(a) If $X$ is a scheme $\mathbb{F}_q$, we will consider

$\alpha$) objects of the derived category $D^b(X, \overline{\mathbb{Q}}_\ell)$

$\downarrow$ by $\sum (-1)^i H^i$

$\beta$) virtual $\ell$-adic sheaves [this means either: elements of the Grothendieck group of the abelian category of constructible sheaves — or if possible and useful, objects of some Picard category having this $K^0$ as set of isomorphism classes of objects]

$\downarrow$ by $\text{Tr}(F_x^*, \mathcal{F}_x)$ (this map is injective)

$\gamma$) “functions”: a system of functions on the $X(\mathbb{F}_q^n)$

(b) Here are corresponding opérations:

on functions: $+, \cdot, \sum$ on $\alpha), \beta)$: $\oplus, \otimes, \mathcal{R}_\pi$!

convolution of functions: if $G$ is a group, and $K, L \in D^b(X, \overline{\mathbb{Q}}_\ell)$, one considers the product

$\pi: G \times G \rightarrow G$, and $K \boxtimes L = \text{pr}_1^* K \otimes \text{pr}_2^* L$, and

$K \ast L = \mathcal{R}_\pi!(K \boxtimes L)$

Kernel: given $Z \rightarrow X \times Y$ and $K \in D^b(Z, \overline{\mathbb{Q}}_\ell)$, this defines an operation $D^b(X) \rightarrow D^b(Y)$

$L_X \mapsto \mathcal{R}_p_{2!}(K \otimes \mathcal{R}_{\pi!} L_X)$.

(c) Now I want to consider Fourier transform.

Let us choose $\psi: \mathbb{F}_p \rightarrow \overline{\mathbb{Q}}_\ell$. If $f$ is a function on $X$, we get a sheaf $\mathcal{F}(\psi f)^1$. Fourier transform, on $G_a$, is given by the kernel $\mathcal{F}(\psi(xy))$ on $G_a \times G_a$.

Definition: $\mathcal{F}(K) = \mathcal{R}_p_{2!}(\mathcal{F}(\psi(xy)) \otimes \mathcal{R}_{\pi!}^*)$

---

1 Pull back by $f$ of the sheaf on $G_a$, rank 1, defined by $\psi$ and Artin–Schreier $T^p - T = X$. 

185
Proposition 1: $\mathcal{F}(K \ast L) = \mathcal{F}(K) \otimes \mathcal{F}(L)$
(from $\mathcal{F}(\psi(x(y + y''))) = \mathcal{F}(\psi(xy')) \otimes \mathcal{F}(\psi(xy''))$)

Proposition 2: $F(K) = K \vee (−1)[−2];$ $\vee$ is for “image by $x \mapsto −x$”, ($−$) for a Tate twist, and $[−]$ for décalage.

Kernels compose like expected: we have to compute $R\pi! \mathcal{F}(\psi(x+z)y)$ for $\pi: \mathbb{G}_a \times \mathbb{G}_a \times \mathbb{G}_a \overset{(13)}{\rightarrow} \mathbb{G}_a \times \mathbb{G}_a$, one gets

$$\begin{cases} Q_\ell(−1) & \text{on the diagonal, in degree 2} \\ 0 & \text{elsewhere} \end{cases}$$

hence the result.

It is convenient in such computations to forget writing $\psi$ and writing $\int \cdots dy$ for a $R\pi!$.

Remark: this defines, via prop 1, an isomorphism $\mathcal{F}(K \otimes L)(−1)[−2] = \mathcal{F}(K) \ast \mathcal{F}(L)$.

For Plancherel formula, one suffer somewhat of not having complex conjugation. Let $\mathcal{F}$ be $F$ defined using $\psi(−x)$. Then

a) inner product: $\langle K, L \rangle = R\Gamma(K \otimes L)$

b) Proposition $\langle FK, FL \rangle = \langle K, L \rangle (−1)[−2]$.

This boils down to the usual

$$\int \psi((x' − x'')y)K(x)L(x'')dx'dx''dy = \int \delta(−1)[−2](x' − x'')K(x)L(x'')(x''dx'dx'').$$

Everything done above can be generalized to any connected unipotent group $U$. The dual $U^*$ is to be taken in Serre’s sense (it is natural only up to inseparable isogenies, but this does not matter. For $n$ large enough, one has a pairing

$$U \times U^* \overset{\cdot}{\rightarrow} W_n$$

(better: the pairing is in the cowitt vectors $W_{−∞} = \lim \leftarrow W_n$). Given $\psi: \mathbb{Q}_p/\mathbb{Z}_p = W_{−∞}(\mathbb{F}_p) \rightarrow \mathbb{Q}_\ell^*$, and using the sheaf given by the Lang covering of $W_{−∞}/\mathbb{F}_p$ and $\psi$, everything can be repeated, with $(−1)[−2]$ replaced by $(-d)[−2d]$ where $d$ is the dimension.

This requires to be careful if one wants to consider $\mathbb{Q}_p$ as a (ind pro quasi) unipotent algebraic group $/\mathbb{F}_p$.

[4] Where $F$ is, there should also be an action of the metaplectic group! (here^3 symplectic). Let me work for $\mathbb{G}_a$, and for $p \neq 2$. The most precise way of speaking I see is working over $\mathbb{F}_p$, with kernels. [It gives more than actions of $\text{SL}(2, k)$ on $\text{D}^b(\mathbb{G}_a, \mathbb{Q}_\ell), k/\mathbb{F}_q$.]

Wanted: $P \in \text{D}^b(\text{SL}(2) \times \mathbb{G}_a \times \mathbb{G}_a)$, viewed as a family of kernels on $\mathbb{G}_a \times \mathbb{G}_a$ parametrized by $\text{SL}(2)$. Plus “$P_{g' \cdot g''} = P_{g' \cdot g''}$”

We know what is wanted for generators:

^2EK: faut-il lire $−1$?

^3EK: c’est ce que je lis.
\[
U^- \begin{pmatrix} 1 & 0 \\ a & 1 \end{pmatrix} \mapsto (\otimes \mathcal{F}(\psi(\frac{ax^2}{2}))) \quad \text{(noyau sur la diagonale)} \\
H \begin{pmatrix} \lambda & 0 \\ 0 & \lambda^{-1} \end{pmatrix} \mapsto (x \mapsto \lambda x)_+() \quad \text{(noyau sur } y = \lambda x) \\
a \neq 0 U^+_0 \begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix} \mapsto \left( \int_x \mathcal{F}(\psi(\frac{a^{-1}x^2}{2})) \right)^{-1} \mathcal{F}(\psi(\frac{a^{-1}x^2}{2}))^* \quad \text{(noyau: faisceau loc } c^l, \text{ de rg } 1, \text{ en degré } -1) \\
\]

An explanation: \( R\Gamma \mathcal{F}(\psi(a^{-1}x^2/2) \) is of dimension 1, and degree 1, and I take the dual one dimensional vector space \([in a]: \text{a sheaf}\), in degree \(-1\).

En français:

Raisonnons un peu a priori. Comme “fonctions”, on sait ce que sont les noyaux cherchés. On cherche des faisceaux leur donnant naissance. Sur \( U^- \times H \times U^+_0 \times U^- \times \mathbb{G}_a \times \mathbb{G}_a \), composant les générateurs, on trouve un faisceau localement constant de rang 1, placé en degré \(-1\), qui convient. En chaque point de \( U^- \times H \times U^+_0 \times U^- \), comme fonction de \( x, y \), il est de la forme \( \psi f \), pour \( f \) une fonction qui, en \( x, y \) (sur \( \mathbb{G}_a \times \mathbb{G}_a \)) est quadratique homogène. Regardons la surjection \( U^- \times H \times U^+_0 \times U^- \longrightarrow G - B^- \quad (G = \text{SL}(2), B^- = (\ast \ast, 0)) \)

Puisque comme “fonctions” ce que nous cherchons existe, le faisceau obtenu est constant sur les fibres de (cette application \( \times \mathbb{G}_a \times \mathbb{G}_a \)).

Obtenu: un faisceau de rang 1, en degré \(-1\), localement constant, sur \( (G - B^-) \times \mathbb{G}_a \times \mathbb{G}_a \).

Pour compléter ce tableau, il est bon de comprendre en quel sens, pour \( a \to 0 \), on a

\[
\left( \int_x \mathcal{F}(\psi(\frac{a^{-1}x^2}{2})) dx \right)^{-1} \cdot \mathcal{F}(\psi(\frac{a^{-1}x^2}{2})) \longrightarrow \delta \quad \text{(faisceau } \mathbb{Q}_\ell \text{ en } x = 0) \\
\]

[ici]

\[
\int \mathcal{F}(\psi(\frac{a^{-1}x^2}{2})) dx \\
\]

est un faisceau de rang 1 (degré \(-1\)) sur la droite de \( a \); ce faisceau se trivialise sur le revêtement de la droite de \( a \) donné par \( \sqrt{a} \), car

\[
\int \mathcal{F}(\psi(\frac{a^{-2}x^2}{2})) dx = \int \mathcal{F}(\psi(\frac{a^{-1}x}{2})^2 dx = \int \mathcal{F}(\frac{x^2}{2}) dx \quad \text{par change de variable} \\
\]

Il correspond à une somme de Gauss; sur \( \int \cdots \), \( |\text{Frobenius}| = q^{1/2} \).

Traçons le plan \( a, x \) ; le faisceau considéré est défini pour \( a \neq 0 \); il se ramifie (sauvagement) le long de \( a = 0 \), et la ramification est équisinguliére pour \( x \neq 0 \). Si \( j \) est l’inclusion de \( a \neq 0 \) dans le plan, on a

\[
\begin{cases}
  j_*(\text{faisceau}) = j_!(\text{faisceau}) & \text{nul pour } a = 0 \\
  R^1j_*(\text{faisceau}) & \text{concentré en } (0, 0), \text{ où c’est } \delta \\
  R^2j_*(\text{faisceau}) & \text{concentré en } (0, 0) 
\end{cases}
\]
Ceci se vérifie assez facilement en éclatant 2 fois (0,0), la 2ème fois en éclatant (courbe exceptionnelle) \( \cap \) (transformé pur de l’axe des \( x \))^4 : on utilise
\[
(\text{plan éclaté}) \quad \tilde{\gamma} \quad \pi \quad (\text{plan} \quad (a \neq 0))
\]
\[
R_{j*} = R\pi_*R\tilde{j}*
\]

On contrôle en projetant sur la droite des \( a \) : si \( p_a \) est cette projection, on a
\[
Rp_a*R_{j*} = R_{j*}Rp_a*
\]
(où \( Rp_a* \) donne \( \mathbb{Q}_\ell \) sur la droite \( a, -\{0\} \), et \( R_{j*} \) sur cette droite \( (a \neq 0) \mapsto a = 0 \), donc
\[
\begin{cases}
\text{deg. } 0 & \mathbb{Q}_\ell \\
\text{deg. } 1 & \mathbb{Q}_\ell(-1) \text{ en } 0.
\end{cases}
\]

Ceci nous dit ce que nous devons faire pour construire \( P \):

(a) sur \( U^+ \), le noyau s’obtient à partir de
\[
\tau_{\leq 0}\left(R_{j*}\left(\left(\mathcal{F}\psi(a^{-1}x^2/2)dx\right)^{-1}\mathcal{F}(\psi(a^{-1}x^2/2))\right)\right)
\]
sur \( U^+ \times \mathbb{G}_a \), comme convolution.

(b) sur \( G \times \mathbb{G}_a \times \mathbb{G}_a \), on prend le noyau déjà construit sur \((G - B^-) \times \mathbb{G}_a \times \mathbb{G}_a\), et pour \( j \) l’inclusion dans \( G \times \mathbb{G}_a \times \mathbb{G}_a \), on lui applique \( \tau_{\leq 0}R_{j*}. \)

Je me suis convaincu que la formule \( P_g \cdot P_{g'} = P_{gg'} \) vaut au sens le plus fort possible:

a) sur \( G \times \mathbb{G}_a \times \mathbb{G}_a \), on prend \( P_{g''}(y, z)P_{g'}(x, y) \).

b) on intègre par rapport à \( y \): \( (P \cdot P)_{g',g''} = \int dy \cdot \cdot \cdot \) sur \( G \times \mathbb{G}_a \times \mathbb{G}_a \)

c) si \( \pi \) est \( G \times G \rightarrow G : g', g'' \mapsto g'g'' \), on a un isomorphisme
\[
(P \cdot P) = \pi^*P
\]

d) on a une compatibilité pour un composé triple [en c), on a unicité à une constante près, et on normalise par ce qui se passe à l’origine].

Bien sûr, tout ceci devrait valoir pour un espace vectoriel \( V \), et \( \text{Sp}(V \oplus V^*) \). Il est facile de se convaincre qu’on a en tout cas un noyau \( P_g(v, v') \) qui est un faisceau virtuel, et que sur la cellule des \( g \in \text{Sp} \) où \( gV^* \cap V^* = 0 \), il est donné de façon naturelle par un faisceau de rang 1, localement constant, en degré \(-n\). J’espère que le noyau lui-même s’en déduit par une suite d’opérations \( \tau_{\leq j*} \), avec un résultat localement constant de rang 1 sur un sous-espace, en degré \(-k\), sur la strate \( \dim(V^*/V^* \cap gV^*) = k \ldots \) (qu’on ait un noyau ainsi stratifié doit pouvoir se vérifier par Fourier).

Question: Le foncteur \( K \mapsto (x \mapsto -x)_!*R\text{Hom}(K, \mathbb{Q}_\ell) \) commute-t-il à l’action de \( \text{SL}(2) \)?

\(^4\text{JF:symbole?}\)
\(^5\text{CHECK}\)
\(^6\text{EK: sic}\)
Question bis: pour $P_g$ le noyau, et $K$ sur $G_a$, a-t-on

\[ Rpr_{2!}(P_g \otimes pr_1^*K) \sim Rpr_{2*}(P_g \otimes pr_1^*K) \quad ? \]

Question ter: y commute-t-il virtuellement – au moins virtuellement sur $\mathbb{F}$ – ?

Bien à toi,

P. Deligne
APPENDIX E

Intuition for analytic number theorists

The goal of this informal appendix is to provide readers with a background in analytic number theory with some intuition and feeling for objects such as ℓ-adic complexes, perverse sheaves, or tannakian categories, all of which are essential tools in this book.

Some familiarity with the theory of trace functions in one variable would be helpful, but is not absolutely necessary. A suitable introduction can be found in the Pisa survey of Fouvry, Kowalski and Michel [36], and a more detailed treatment is contained in the lectures of Ph. Michel at the 2016 Arizona Winter School [38].

We fix a finite field \( k \), and denote by \( k_n \) the extension of \( k \) of degree \( n \) in a fixed algebraic closure \( \bar{k} \). For simplicity of notation, we will mostly speak about trace functions on the affine \( m \)-space \( \mathbb{A}^m \) for some integer \( m \geq 0 \). However, it will be implicit that most of what we discuss can be done for any algebraic variety \( Y \) over \( k \) (and this is needed, for instance because we often naturally wish to restrict a trace function to a subvariety, where some particular property holds), for instance for powers of the multiplicative group \( G_m \) (i.e., \( Y \) such that \( Y(k_n) = (k_n)^d \) for some \( d \geq 0 \)).

The reader should keep in mind that for such a subvariety, of dimension \( d \leq m \), the size of the finite set \( Y(k_n) \) of points of \( Y \) with coefficients in \( k_n \) is approximately \( |k_n|^d \) when \( n \) is large.

Throughout, we fix a non-trivial additive character \( \psi: k \to \mathbb{C}^\times \), and for \( n \geq 1 \), we define \( \psi_n: k_n \to \mathbb{C}^\times \) by

\[
\psi_n(x) = \psi(\text{Tr}_{k_n/k}(x)).
\]

We finally note that we will completely ignore the distinction between \( \mathbb{Q}_\ell \) and \( \mathbb{C} \).

E.1. Trace functions

The concrete origin for the use of methods of algebraic geometry and étale cohomology in analytic number theory lies in trace functions, and especially in exponential sums. Properly speaking, a trace function on \( \mathbb{A}^m \) is the data of a family \( (t_n)_{n \geq 1} \) of functions \( k_m \to \mathbb{C} \), and it is associated to some algebraic object \( M \), which we call a “coefficient object”. This object is not uniquely determined by \( (t_n) \), but we will usually not worry about this matter.

The simplest examples of trace functions are associated to a polynomial \( f \in k[X_1, \ldots, X_m] \), and given by

\[
t_n(x_1, \ldots, x_m) = \psi_n(f(x_1, \ldots, x_m)) ;
\]

the corresponding coefficient is denoted \( \mathcal{L}_{\psi(f)} \).

Many other examples are then obtained by applying various operations, which are known to preserve the set of trace functions (these are operations on the coefficients, which are reflected in a specific operation at the level of trace functions). These operations include the following, where we indicate the algebraic notation for the corresponding coefficients:

- The constant function 1 is associated to the coefficient \( M = \mathbb{Q}_\ell \).
- The sum of the trace functions associated to $M_1$ and $M_2$ is associated to $M_1 \oplus M_2$.

- If $(t_n)$ is a trace function associated to $M$, then for any integer $k \geq 0$, the functions $((-1)^k t_n)$ are trace functions associated to a coefficient denoted $M[k]$ (the operation $M \mapsto M[1]$ is called a “shift”).

- The product of the trace functions associated to $M_1$ and $M_2$ is associated to $M_1 \otimes M_2$.

- If $f = (f_1, \ldots, f_d): A^m \to A^d$ is a tuple of polynomials in $k[X_1, \ldots, X_m]$, and $s = (s_n)$ is a trace function on $A^d$, associated to a coefficient $N$, then
\[
t_n(x_1, \ldots, x_m) = s_n(f(x_1, \ldots, x_m))
\]
defines a trace function $(t_n)$ on $A^m$, which we also denote $s \circ f$. The corresponding coefficient is $f^*N$.

- If $f = (f_1, \ldots, f_d): A^m \to A^d$ is a tuple of polynomials in $k[X_1, \ldots, X_m]$, and $t = (t_n)$ is a trace function on $A^m$, associated to a coefficient $M$, then
\[
(E.2) \quad s_n(y_1, \ldots, y_d) = \sum_{x \in k_m^n} t_n(x) \quad \text{for } f(x) = y
\]
defines a trace function on $A^d$; the associated coefficient is denoted $Rf_!M$.

**Example E.1.** This formalism is already sufficient to explain Deligne’s Fourier transform. Consider $m \geq 1$ and the projections
\[
p_1, p_2: A^{2m} \to A^m
\]
such that
\[
p_1(x_1, \ldots, x_m, y_1, \ldots, y_m) = (x_1, \ldots, x_m), \quad p_2(x_1, \ldots, x_m, y_1, \ldots, y_m) = (y_1, \ldots, y_m).
\]

We denote
\[
X \cdot Y = X_1 Y_1 + \cdots + X_m Y_m
\]
for variables $X_i$ and $Y_j$. This is a polynomial with coefficients in $k$, so the functions
\[
F_n(x, y) = \psi_n(x_1 y_1 + \cdots + x_m y_m)
\]
define a trace function $F = (F_n)$ on $A^{2m}$, associated to the coefficient $\mathcal{L}_\psi(X \cdot Y)$.

Let $t = (t_n)$ be a trace function on $A^m$. Then the discrete Fourier transforms $(\hat{t}_n)$, which are defined for $n \geq 1$ and $y \in k_m^n$ by
\[
\hat{t}_n(y) = \sum_{x \in k_m^n} t_n(x) F_n(x, y) = \sum_{x \in k_m^n} t_n(x) \psi_n(x \cdot y)
\]
also define a trace function $\hat{t} = (\hat{t}_n)$. Indeed, for any $y$, the set of all $x \in k_m^n$ can be identified with the set of $(x, y) \in k^{2m}$ such that $p_2(x, y) = y$, and we have $t_n(x) = t_n(p_1(x, y))$, so that if $t$ is associated to the coefficient $M$, then the formalism above shows that $\hat{t}$ is associated to
\[
\hat{M} = Rp_2!(p_1^* M \otimes \mathcal{L}_\psi(X \cdot Y)).
\]
E.2. Weights and purity

Trace functions and the formalism they satisfy are useful in analytic number theory because of Deligne’s Riemann Hypothesis over finite fields. This also leads to some understanding of the important qualitative differences between various types of trace functions – corresponding to classes of coefficients which may (for instance) be lisse sheaves, constructible sheaves, complexes of constructible sheaves, or perverse sheaves. We will try in this and the following sections to provide some intuition of the concrete meaning of such names.

The key concept (due to Deligne) is that of a coefficient $M$ which is pure of some weight $w \in \mathbb{Z}$. The key conceptual difficulty is that the meaning of this property for the corresponding trace function is not straightforward in general.

The simplest case (from which the others will be constructed) is that of $M$ which is a single “lisse sheaf”. The concrete meaning, in terms of the trace function $t = (t_n)$ of $M$ being of weight $w$ in that case is that there exists an integer $r \geq 0$, the rank of $M$, and for each $n \geq 1$ and $x \in k_n^m$, there exists a unitary matrix $\Theta_M(x; k_n) \in U_r(\mathbb{C})$, well-defined up to conjugacy, so that

$$t_n(x) = |k_n|^{w/2} \operatorname{Tr}(\Theta_M(x; k_n)).$$

In particular, note that this implies that

$$|t_n(x)| \leq r |k_n|^{w/2}$$

for all $n$ and $x \in k_n^m$.

Remark E.2. In fact, the matrix $\Theta_M(x; k_n)$ is not arbitrary: its eigenvalues (which of course determine the trace) are Weil numbers of weight 0, i.e., algebraic numbers in $\mathbb{C}$ for which all Galois conjugates have modulus 1.

Moreover, if $n'$ is a multiple of $n$, then $x \in k_n^m$ can also be viewed as an element of $k_n^m$, and the formula

$$\Theta_M(x; k_n') = \Theta_M(x; k_n)^{n'/n}$$

holds (in other words, the eigenvalues of $\Theta_M(x; k_n')$ are those of $\Theta_M(x; k_n)$ raised to the power $n'/n$).

As one can expect, the “simplest trace functions” defined by the formulas (E.1), associated to $L_{\psi(f)}$, are of this type, with $r = 1$, $w = 0$, and the matrix $\Theta(x; k_n)$ reduced to the single complex number of modulus one $\psi_n(f(x))$. Moreover, it is also intuitively clear (and true) that some of the operations discussed above will respect the special class of trace functions associated to pure lisse sheaves.

For instance:

- If $t$ and $t'$ are trace functions associated to objects $M$ and $N$ which are both lisse sheaves pure of weight $w$, then $t + t'$ is also pure of weight $w$.

- If $s$ and $t$ are trace functions associated to objects $M$ and $N$ which are both lisse sheaves pure of weights $w$ and $w'$, then $tt'$ is also pure of weight $w + w'$. (In other words, $M \otimes N$ is still a lisse sheaf, pure of that weight.)

- If $f = (f_1, \ldots, f_d): A^m \to A^d$ is a tuple of polynomials in $k[X_1, \ldots, X_m]$, and $s$ is a trace function on $A^d$ associated to a lisse sheaf of weight $w$, then $s \circ f$ is also pure of weight $w$. (In other words, $f^*N$ is still a lisse sheaf, pure of weight $w$.)

But elementary examples show that the crucially important operation of “summing over the fiber” (see (E.2)) does not always send a single lisse sheaf to a lisse sheaf, and may also not map a trace function which is pure of some weight to another one.
Example E.3. (1) Let \( m = n = 1 \) and \( f \in k[X] \) a separable polynomial of degree 2. We consider the trace function \( (t_n) \) with \( t_n(x) = \psi_n(x) \), associated to the lisse sheaf \( L_{\psi(X)} \) (of weight 0), and the trace function \( (s_n) \) defined by

\[
s_n(x) = \sum_{y \in k_n} t_n(y) = \sum_{y \in k_n} \psi_n(y),
\]

for \( n \geq 1 \) and \( x \in k_n \), which is associated to \( Rf_!L_{\psi(X)} \). For most \( x \), this is either 0 or a sum of two roots of unity, but for the single point \( x_0 = f(y_0) \), where \( y_0 \) is the unique zero of the derivative of \( f \), the value \( s_n(x_0) \) is a single root of unity.

(2) We consider \( m = 2 \) and the trace function \( (t_n) \) defined by \( t_n(x, y) = \psi_n(xy^2) \) for \( (x, y) \in k_n^2 \). It is associated to \( L_{\psi(XY^2)} \), which is pure of weight 0. Let \( n = 1 \) and \( f = X \). Then \( Rf_!L_{\psi(XY^2)} \) has the trace function \( (s_n) \) such that

\[
s_n(x) = \sum_{y \in k_n} \psi_n(xy^2) = \begin{cases} 
\text{a quadratic Gauss sum} & \text{if } x \neq 0, \\
|k_n| & \text{if } x = 0.
\end{cases}
\]

Neither of these examples of trace functions are associated to a single pure lisse sheaf. However, it turns out that the underlying reason is not the same for both of them. In Example (1), the issue is that \( (s_n) \) is associated to a single constructible sheaf which is “not lisse” at the point \( x_0 \). In Example (2), the issue is that \( (s_n) \) is associated to a “complex” of constructible sheaves, i.e., not to a single sheaf.

E.3. Constructible sheaves and complexes

In fact, the most general sources of trace functions are (bounded) complexes of constructible sheaves. We now try to outline the concrete interpretation of these more general conditions.

The first step goes from a single lisse sheaf to a single constructible sheaf, pure of weight \( w \). This means that there is a “stratification”

\[
\emptyset = X_0 \subset X_1 \subset \cdots \subset X_q = A^m
\]

of \( A^m \), where each \( X_i \) is a proper subvariety of \( X_{i+1} \), so that the restriction of \( M \) to each of the pieces \( X_{i+1} - X_i \) is a single lisse sheaf, pure of weight \( w \), and of some rank \( r_i \geq 0 \) (which may depend on \( i \)).

Concretely, for a given \( x \in k_n^m \), there exists an \( i \) such that \( x \in X_{i+1} - X_i \), and then there exists a unitary matrix \( \Theta_M(x; k_n) \) of size \( r_i \) such that

\[
\psi_n(x) = |k_n|^{w/2} \text{Tr}(\Theta_M(x; k_n)).
\]

Example E.4. Example (1) above is of this kind, with the stratification

\[
\emptyset \subset \{x_0\} \subset A^1,
\]

and with \( r_0 = 1 \) and \( r_1 = 2 \). On \( \{x_0\} \), the unique eigenvalue is \( s_n(x_0) = \psi_n(y_0) \) (viewing \( x_0 \) as belonging to \( k_n - x_0 \) note that \( x_0 \in k \), hence belongs to all \( k_n \), but the value of \( t_n(x_0) \) does vary with \( n \). On \( A^1 - \{x_0\} \) the two eigenvalues are either opposite (hence the trace is zero) if \( x \notin f(k_n) \), or are given by \( \psi_n(y) \), for \( y \) ranging over the two roots of the quadratic equation \( f(y) = x \).

More generally, Deligne defined a mixed constructible sheaf of weights \( \leq w \) by the condition that there is a filtration with associated pure quotients \( M_j \), each of some weight \( w_j \leq w \). Concretely,
this translates to the fact that the trace function \( t = (t_n) \) is given by

\[
t_n(x) = \sum_{j \in J} t_{n,j}(x)
\]

for some finite set \( J \), where each family \( (t_{n,j})_{n \geq 1} \) is the trace function of a constructible sheaf which is pure of weight \( w_j \leq w \).

Finally, the most general type of trace functions arises from objects \( M \) that are complexes of constructible sheaves. This means that \( M \) is built (in some sophisticated algebraic way) out of a sequence \( (\mathcal{H}^i(M))_{i \in \mathbb{Z}} \) of constructible sheaves, with \( \mathcal{H}^i(M) = 0 \) for all but finitely many \( i \), in such a way that

\[
t_n(x) = \sum_{i \in \mathbb{Z}} (-1)^i t_{n,i}(x)
\]

for all \( n \geq 1 \) and \( x \in \k_n \), where \( (t_{n,i})_{n \geq 1} \) is the system of trace functions for the constructible sheaf \( \mathcal{H}^i(M) \). (These sheaves are called the cohomology sheaves of the complex \( M \).)

**Example E.5.** Example (2) above is obtained from a complex of constructible sheaves \( M \), where there are two non-zero pieces, namely \( \mathcal{H}^1(M) \) and \( \mathcal{H}^2(M) \).

The sheaf \( \mathcal{H}^1(M) \) is constructible for the stratification

\[\emptyset \subset \{0\} \subset A^1,\]

with the piece on \( \{0\} \) of rank 0, and the piece on \( A^1 - \{0\} \) of rank 1, pure of weight 1, with the corresponding unique eigenvalue equal to the quadratic Gauss sum

\[
\sum_{y \in k_n} \psi_n(xy^2)
\]

for \( x \in k_n - \{0\} \).

The sheaf \( \mathcal{H}^2(M) \) is also constructible for the same stratification, with the lisse sheaf of rank 0 on \( A^1 - \{0\} \), and a piece of rank 1 of weight 2 at \( \{0\} \), with eigenvalue \(|k_n|\) (when computing \( t_n(0) \)).

However, for a complex \( M \), the condition that ensures that \( M \) is pure of weight \( w \) is much more subtle. More precisely, one defines first the mixed complexes of weights \( \leq w \), which are those such that \( \mathcal{H}^i(M) \) is a mixed constructible sheaf of weights \( \leq w + i \) for any \( i \in \mathbb{Z} \). There is then furthermore defined another complex \( D(M) \), called the Verdier dual of \( M \), and \( M \) is said to be pure of weight \( w \) if both \( M \) and \( D(M) \) are mixed of weights \( \leq w \).

**Remark E.6.** (1) For a single lisse sheaf \( M \) which is pure of weight 0, the corresponding complex has \( \mathcal{H}^0(M) = M \) and \( \mathcal{H}^i(M) = 0 \) for all \( i \neq 0 \). One can prove that the Verdier dual is still a single lisse sheaf which is pure of weight 0 (in fact, its trace function is in this case the complex conjugate of the trace function of \( M \)), so that the two definitions of purity coincide for lisse sheaves.

(2) In practice, if an analytic number theorist is interested in a single trace function (e.g., one that represents a concrete family of exponential sums which one is interested in estimating, for instance the hyper-Kloosterman sums

\[
K_{3\ell}(x; k_n) = \sum_{a,b,c \in k_n^* \atop abc=x} \psi_n(a + b + c),
\]

1 This fact is not a general feature.

2 In particular, it does not mean that each piece \( \mathcal{H}^i(M) \) is itself pure of weight \( w \).
or the famous sums

\[ \text{FI}(x, y; k_n) = \sum_{z \in k_n^\times} K_3(xz; k_n) K_3(yz; k_n) \psi_n(z) \]

which arose in the work of Friedlander and Iwaniec on the ternary divisor function \([41]\), and reappeared in the work of Zhang \([114]\), and one is not applying further operations like \(Rf_i\), then one can quite often reduce to the case of a single lisse sheaf.

Indeed, if the exponential sum is mixed, this will often be clear from the definition, or from a preliminary analysis, and one can “isolate” the part of most interest (of highest weight usually), which will be associated to a pure constructible sheaf. Then by restricting the set of definition according to a suitable stratification, one will ensure that one handles a lisse sheaf.

For \(m = 1\), this second step means avoiding finitely many values of \(x\) where the sheaf has unusual behavior; for \(m \geq 2\), this means avoiding those that satisfy some non-trivial polynomial equation \(g(x_1, \ldots, x_m) = 0\). These special parameters can then be handled separately – giving rise to a kind of inductive process which reflects exactly the algebraic stratification of the corresponding coefficient \(M\).

One good explanation for the focus on mixed objects with bounded weights can be found (a posteriori) from the statement of Deligne’s most general form of the Riemann Hypothesis. In our context, it can be stated as follows:

**Theorem E.7** (Deligne). Let \((t_n)\) be a trace function on \(A^m\) associated to a complex \(M\) which is mixed of weights \(\leq w\). Let \(f = (f_1, \ldots, f_d)\) be a tuple of polynomials in \(k[X_1, \ldots, X_m]\). The trace function

\[ s_n(y) = \sum_{x \in k_n^m \atop f(x) = y} t_n(x) \]

associated to \(Rf_!M\) is mixed of weights \(\leq w\).

**Remark E.8.** On the other hand, even if \(M\) is a single lisse sheaf, pure of weight \(w\), it is not always the case that \(Rf_!M\) is pure.

The benefit of introducing these more general definitions is that all operations now respect the property of being mixed for any trace function, with a good understanding of how the weights may change:

- The lisse sheaf \(M = \overline{Q}_\ell\) is pure of weight 0.
- If \(M_1\) and \(M_2\) have weights \(\leq w_1\) and \(w_2\), respectively, then \(M_1 \oplus M_2\) has weights \(\leq \max(w_1, w_2)\) and \(M_1 \otimes M_2\) has weights \(\leq w_1 + w_2\).
- If \(M\) has weights \(\leq w\), then for any \(k \in \mathbb{Z}\), the shifted complex \(M[k]\) has weights \(\leq w - k\).
- If \(f = (f_1, \ldots, f_d)\): \(A^m \to A^d\) is a tuple of polynomials in \(k[X_1, \ldots, X_m]\), and \(s = (s_n)\) is a trace function on \(A^d\) associated to a mixed complex \(N\) of weights \(\leq w\), then \(f^*N\) has weights \(\leq w\).
- If \(f = (f_1, \ldots, f_d)\): \(A^m \to A^d\) is a tuple of polynomials in \(k[X_1, \ldots, X_m]\), and if \(M\) has weights \(\leq w\), then \(Rf_!M\) has weights \(\leq w\) (this is again Deligne’s Theorem).
All objects that occur in practice in analytic number theory\(^3\) are mixed complexes. This means that any trace function \((t_n)\) has a decomposition

\[ t_n = \sum_{a \leq w \leq b} t_{n,w} \]

for some \(a\) and \(b\) (independent of \(n\)), where \((t_{n,w})_{n \geq 1}\) is a trace function associated to a complex which is pure of weight \(w\).

**E.4. Perverse sheaves**

There remains the task of attempting to explain a further fundamental subclass of trace functions (hence of complexes), those associated to perverse sheaves. This is a distinguished class of complexes with remarkable geometric and arithmetic properties. For analytic purposes, the most important of these is maybe that the simple perverse sheaves provide a canonical basis of the abelian group of trace functions, and that if we restrict to pure perverse sheaves, then this is in a natural sense a quasi-orthogonal basis for the trace functions of pure complexes of weight 0. We will now explain these properties.

The rigorous definition of perverse sheaves is of a similar nature to that of pure complexes: it is the combination for both the complex \(M\) and its Verdier dual \(D(M)\) of a relatively simple condition, called semiperversity.\(^4\) The condition of semiperversity concerns the size of the support of the cohomology sheaves \(H^i(M)\), which are intuitively the points \(x\) where \(H^i(M)\) does not vanish (in the stratification in lisse sheaves, this is where these sheaves have non-zero rank): for any \(i \in \mathbb{Z}\), the support of \(H^i(M)\) should be of dimension at most \(-i\). (In particular, if \(i \geq 1\), then the support should be empty, so \(H^i(M)\) should be zero then.)

Remarkably, this condition can be recovered intuitively from basic analytic intuition (which highlights that it is extremely natural).

Thus consider a trace function \(t = (t_n)\) associated to a complex \(M\) on \(\mathbb{A}^m\) and assume that it is mixed of weights \(\leq 0\). From the analytic point of view, we are often in the situation where the mean-square of the values of the trace function \(t_n\) are bounded (after some normalization maybe), and bounded away from zero, i.e., for \(n\) large enough, we have

\[
\sum_{x \in k_n} |t_n(x)|^2 \asymp 1.
\]

(E.3)

For \(i \in \mathbb{Z}\), the cohomology sheaf \(H^i(M)\) should be “essentially” pure of weight \(i\) (rigorously, we only know that it is mixed of weights \(\leq i\)). So the contribution to the sum above of the \(x\) in the support \(S_i\) of \(H^i(M)\) should be expected to be of order of magnitude

\[ |k_n|^{2i/2} \times |S_i(k_n)| \approx |k_n|^{i+d_i} \]

if \(S_i\) has dimension \(d_i\). Hence the estimate (E.3) only has a chance to hold if \(i + d_i \leq 0\) for all \(i\), and this is precisely the semiperversity condition.

**Example E.9.** Consider a family of exponential sums of type

\[
\frac{1}{|k_n|^m} \sum_{y \in k_n^m} \psi_n(f(y) + x_1y_1 \cdots + x_my_m)
\]

with parameters \((x_1, \ldots, x_m) \in k_n^m\) (these functions of \(x\) are the trace functions of a complex \(M\) which is a normalized form of Deligne’s Fourier transform of the lisse sheaf \(\mathcal{L}_{\psi(f)}\)).

\(^3\) And indeed more generally in algebraic geometry.

\(^4\) The difficulty being that the Verdier dual is very often extremely difficult to compute.
We expect “generic” square-root cancellation, so as \( n \) varies, for “most” choices of \( x \in \mathbb{k}^m \), this sum should be of size about \( |\mathbb{k}_n|^{-m/2} \). Since \( \mathcal{H}^i(M) \) is of weight \( \leq i \), so contributes terms of size typically expected to be \( |\mathbb{k}_n|^{-m/2+1/2} \), this expectation corresponds to the fact that \( \mathcal{H}^i(M) \) should be “generically” zero, while \( \mathcal{H}^{-m}(M) \) contributes a fixed number of complex numbers of modulus \( \leq |\mathbb{k}_n|^{-m/2} \).

But for special values of \( x \), those satisfying some non-trivial polynomial equation \( g(x) = 0 \), one may obtain a larger sum than square-root cancellation. Experience teaches that usually this size only jumps by one factor \( |\mathbb{k}_n|^{1/2} \) (so the sum is about \( |\mathbb{k}_n|^{-m/2+1/2} \)) if only this one condition is imposed; if it is bigger (say of size \( |\mathbb{k}_n|^{-m/2+1} \)), this should mean that a second (independent) equation \( h(x) = 0 \) holds, and so on.

This “stratification” of bounds getting steadily worse only on smaller subsets corresponds to cohomology sheaves \( \mathcal{H}^i(M) \) (contributing terms of size \( |\mathbb{k}_n|^{i/2} \)) vanishing outside of subvarieties of dimension at most \(-i\).

In the extreme case, the exponential sum is of size 1, i.e., there is no cancellation at all, at worse for finitely many values of the parameters, corresponding to \( \mathcal{H}^0(M) \) being supported on finitely many points.

This particular example is at the root of the results of Katz, Laumon and Fouvry on stratification for additive exponential sums [34, 71, 35]. It should suggest to analytic readers that semiperversity is a relatively easy condition to check, and that it should be natural and ubiquitous in analytic number theory.

The following statement provides the first concrete illustration of the advantages of perverse sheaves.

**Theorem E.10.** The \( \mathbb{Z} \)-module of trace functions on \( \mathbb{A}^m \) over \( k \) is generated by the trace functions of perverse sheaves, and the trace functions of simple perverse sheaves form a basis.

The first statement is in fact very explicit. Indeed, if \( t = (t_n) \) is an arbitrary trace function, associated to a complex \( M \), one can define (in addition to its “usual” cohomology sheaves \( \mathcal{H}^i(M) \)) its **perverse cohomology sheaves** \( ^p\mathcal{H}^i(M) \), which are perverse sheaves, zero for \( |i| > m \), such that their trace functions \( (^p\!t_{i,n})_{n \geq 1} \) satisfy the equation

\[
t_n = \sum_{i \in \mathbb{Z}} (-1)^i \, ^p\!t_{i,n}
\]

for all \( n \geq 1 \). Furthermore, a complex \( M \) is mixed of weights \( \leq w \) if and only if each \( ^p\mathcal{H}^i(M) \) is also mixed of weights \( \leq w + i \) (similarly to the cohomology sheaves; see [6, Th. 5.4.1]).

**Remark E.11.** To say that \( M \) is perverse is to say that \( M = ^p\!t^0(M) \) and \( ^p\!t^i(M) = 0 \) for all \( i \neq 0 \).

Up to the terminology and notation, the second statement of Theorem E.10 is proved by Laumon in [87, Th. 1.1.2] (it was already mentioned by Deligne in his letter to Kazhdan, see Appendix D). To understand it, one must explain what are the simple perverse sheaves that are mentioned there. We will content ourselves with stating the quasi-orthonormality property that holds for a simple perverse sheaf that is pure of weight 0. It is another consequence of Deligne’s Riemann Hypothesis, proved by Katz, that if \( t = (t_n) \) is the trace function of a perverse sheaf \( M \), then we have

\[
\limsup_{n \to +\infty} \sum_{x \in \mathbb{k}^m} |t_n(x)|^2 = 1
\]

if and only if \( M \) is simple.
Remark E.12. One of the fundamental results of Beilinson, Bernstein, Deligne and Gabber [6, Cor. 5.3.4] is that a simple perverse sheaf which is mixed, as a complex, is in fact pure of some weight; since non-mixed complexes do not appear in practice, this means that simple perverse sheaves in analytic number theory are always pure of some weight, and the quasi-orthonormality characterization can be extended to all simple perverse sheaves, up to normalization.

Example E.13. We can illustrate how useful this quasi-orthonormality statement can be to guess or understand some properties of perverse sheaves by noting that it strongly suggests a non-trivial property of simple perverse sheaves. Namely, let $M$ be a simple perverse sheaf, pure of weight 0, and generically non-zero (i.e., the support of $M$ is all of $A^m$). If we repeat the argument leading to the guess of the semiperversity condition, we see that we expect that the contribution to

$$\sum_{x \in k^n_m} |t_n(x)|^2$$

of each non-zero cohomology sheaf $H^i(M)$ should be of size

$$\alpha_i |k_n|^{|i|+d_i}$$

for some integer $\alpha_i \geq 1$, and comparison with (E.4) indicates that $i + d_i$ will be $< 0$ except for one single value of $i$. Moreover, one knows that the cohomology sheaf $H^{-m}(M)$ is generically non-zero, so this value must be $i = -m$, so that we expect that

$$d_i \leq -i - 1 \quad \text{for} \quad i \neq -m.$$ 

This is indeed true (it is the improved support condition of Proposition A.13).

E.5. Tannakian categories

The results of this book also rely in an essential way on another tool that is most likely unfamiliar to analytic number theorists: the formalism of tannakian categories. In very rough terms, this refers to a method to construct or define a group (which in our case will be the “symmetry group” that governs the equidistribution properties of a trace function), by recovering it from the way it acts on finite-dimensional K-vector spaces, where K is an algebraically closed field (which can be considered to be $C$).

That this is possible is indicated by the following result:

Theorem E.14 (Tannaka). Let $G$ be a compact group. Assume that, for every finite-dimensional $C$-vector space $V$ on which the group $G$ acts linearly, via a continuous homomorphism $\varrho: G \to GL(V)$, we are given an invertible linear transformation $\alpha(\varrho): V \to V$, and suppose that these data satisfy the following condition:

“Whenever $G$ acts by $\varrho$ on $V$ and by $\pi$ on $W$, we have

$$\alpha(\varrho \otimes \pi) = \alpha(\varrho) \otimes \alpha(\pi)$$

and whenever we have a linear map $u: V \to W$ such that

$$u(\varrho(g)v) = \pi(g)u(v)$$

for all $g \in G$ and $v \in V$, then we have

$$u \circ \alpha(\varrho) = \alpha(\pi) \circ u$$

as linear maps from $V$ to $W$.”

Then there exists a unique element $g \in G$ such that $\alpha(\varrho) = \varrho(g)$ for all actions $\varrho$ of $G$. 

199
More generally, note that the “set” of all data of all $\alpha(\varrho)$ of the type considered in this theorem can naturally be used to form a group (with $(\alpha \beta)(\varrho) = \alpha(\varrho) \circ \beta(\varrho)$), and then the result identifies the group $G$ with these data.

In a converse direction, the main theorem of the theory of tannakian categories establishes a list of conditions on a suitable category which guarantees that it is “equivalent” to the category of representations of a group $G$ (although the context is that of algebraic groups, such as $\text{GL}_n(\mathbb{C})$, instead of compact groups). A key property to apply the “reconstruction theorem” is that one must be able to associate to each object $M$ a finite-dimensional vector space $\omega(M)$ (corresponding to the abstract space on which the group acts), and one needs to have defined a bilinear operation on these objects, say $M \star N$, in such a way that $\omega(M \star N) = \omega(M) \otimes \omega(N)$. Such an “assignment” $\omega$ is called a fiber functor; it is not unique, and its construction may be a delicate matter.

In the applications in this book (following the idea of Katz in [68]), the objects that will correspond in this abstract way to the actions of $G$ on vector spaces are certain perverse sheaves, and the operation $\star$ is a form of algebraic convolution which respects the corresponding usual convolution operation on trace functions.

For an accessible treatment of tannakian categories, emphasizing the natural evolution from Galois theory, see the book [110] of Szamuely.

E.6. Catechism

We conclude by trying to answer some natural questions that an analytically-minded reader of little faith may raise:

- **Why are perverse sheaves essential to the results of this book? Why can one not (even in the simplest cases, such as exponential sums parameterized by multiplicative characters) work around the requirement to use such objects in a way similar to the previous papers of Fouvry, Kowalski and Michel?**

  The simplest reason for this (not the only one) is that the use of tannakian methods (which is the only way we know to produce the symmetry group for arithmetic Fourier transforms) depends on applying many times a number of operations which will have uncontrollable effect on the type of complex we work with, even when starting with a simple lisse sheaf.

  More technically, the same tannakian idea requires the construction of an abelian category (which will “be” the category of representations of the symmetry group); general complexes do not form an abelian category, whereas perverse sheaves form one – certainly the best known abelian category beyond that of lisse sheaves.

- **Conversely, if perverse sheaves are so natural and have such remarkable properties, and suffice to describe all trace functions, why not dispense with general complexes then?**

  Here the issue is that, although perverse sheaves and their trace functions are individually wonderful things, they are not in toto stable by all the operations that one might want to apply. In particular, if $M$, $M_1$, $M_2$ and $N$ are perverse sheaves, then it is not true in general that $M_1 \otimes M_2$, or $f^*N$, or $Rf_!M$, are perverse sheaves (on their respective affine spaces). (A significant and highly non-trivial exception, however, is that if $M$ is perverse on $A^m$, then its Fourier transform in the sense of Deligne is still perverse.) In the case of our applications, the problem appears in the definition of the algebraic convolution that is used to apply the tannakian formalism – a priori, even for $M$ and $N$ perverse, their algebraic convolution is simply a complex of constructible sheaves.
Why is there no normalization by the size of the sum in a formula like (E.4)?

It is a useful property of perverse sheaves, although surprising at first sight, that the definition itself implies a normalization for these sums. If $M$ is a perverse sheaf with support $\mathbf{A}^m$ which is pure of weight 0, then the local eigenvalues at a “generic” point $x$ of $k_n^m$ are of weight $-m$, i.e., they are typically of size $|k|^{-m/2}$. So the sum (E.4) is naturally expected to be of bounded size, without normalizing.

e neutral element of a group, 22
exp(2πi) 12
<table>
<thead>
<tr>
<th>Notation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F(X)</td>
<td>Fano variety of lines, 161</td>
</tr>
<tr>
<td>f ≈ g</td>
<td>asymptotic notation, 12</td>
</tr>
<tr>
<td>f ≍ g</td>
<td>asymptotic notation, 12</td>
</tr>
<tr>
<td>f ∼ g</td>
<td>asymptotic notation, 12</td>
</tr>
<tr>
<td>J_S</td>
<td>generalized jacobian, 122</td>
</tr>
<tr>
<td>K(X) = K(X, Q)</td>
<td>Grothendieck group, 14</td>
</tr>
<tr>
<td>K*</td>
<td>set of conjugacy classes in K, 73</td>
</tr>
<tr>
<td>K_neg(G)</td>
<td>subgroup of K(G) generated by negligible objects, 54</td>
</tr>
<tr>
<td>m</td>
<td>group law, 22</td>
</tr>
<tr>
<td>M * N</td>
<td>convolution, 22</td>
</tr>
<tr>
<td>M * N</td>
<td>convolution with compact support, 22</td>
</tr>
<tr>
<td>M *int N</td>
<td>internal convolution, 56</td>
</tr>
<tr>
<td>M^∨</td>
<td>tannakian dual of M, 23</td>
</tr>
<tr>
<td>M_2m(G)</td>
<td>M_2m(G, Std), 115</td>
</tr>
<tr>
<td>M_2m(G, V)</td>
<td>2m-th absolute moment of the representation V of G, 115</td>
</tr>
<tr>
<td>M^x</td>
<td>twist of M by ( \mathcal{L}_x ), 25</td>
</tr>
<tr>
<td>M_{int}</td>
<td>quasi-inverse of ( P_{int}(G) \to \bar{P}(G) ), 56</td>
</tr>
<tr>
<td>( N_{k_n/k} )</td>
<td>norm map, 23</td>
</tr>
<tr>
<td>S(M, x)</td>
<td>arithmetic Fourier transform, 26</td>
</tr>
<tr>
<td>t_M(x) = t_M(x; k)</td>
<td>trace function of M on X(k), 14</td>
</tr>
<tr>
<td>t_M(x; k_n)</td>
<td>trace function of M on X(k_n), 14</td>
</tr>
<tr>
<td>U*</td>
<td>Serre dual, as group scheme, 35</td>
</tr>
<tr>
<td>U^∨</td>
<td>algebraic group model of the Serre dual, 35</td>
</tr>
