Corrections

Here are the currently known corrections; those which are mathematically significant are marked with a star.

(1) Page 3, line 2: U. Schapira should be U. Shapira.
(2) (*) Pages 32, 34: Zorn’s Lemma states that there is a maximal element in any non-empty ordered set where every non-empty totally ordered subset $S$ has an upper bound; page 32, for instance, the assumption that $S$ is not empty is necessary to check that the subspace $\tilde{F}$ of line -5 is a linear subspace.
(3) Page 115, line 4: $x$ should be in $M_{n}(k)$ and $g$ in $GL_{n}(k)$, instead of the opposite.
(4) Page 197, line -3: the variable $y$ in the sum should be $x$.
(5) Page 205, line -2: there is an extra parenthesis in $a \pmod{q}$.
(6) Page 219, middle of the page, display: $\chi$ instead of $\text{chi}$.
(7) Page 241, line 1: “Nikolo” should be “Nikolov”.
(8) Page 338, line 19: $SU_{3}(C)$ instead of $U_{3}(C)$.
(9) Page 351, line -7: $\Psi_{1}$ should be $\psi_{1}$ twice in the formula.
(10) (*) Page 402, line 1: $\exp(-X) = \exp(X)^{-1}$ instead of $\exp(-X) = \exp(X)$.
(11) Page 422, reference [31]: “Théorie” instead of “ThÉorie”.
(12) Page 423, reference [56]: add space before the title.

Additions

After Exercise 4.5.4, add the following Example 4.5.5.

Example 4.5.5 (Characterization of cyclic Galois extensions) As an application of the representations of finite abelian groups, we explain a proof of an important result from elementary Galois theory: the classification of cyclic Galois extensions when the degree is coprime to the characteristic of the base field and we have enough roots of unity. Readers who are unfamiliar with Galois theory can skip this example.

Proposition 4.5.6 Let $K$ be a field of characteristic $p$ and $L/K$ a finite Galois extension of degree $n \geq 1$ coprime with $p$. Assume that $K$ contains a primitive $n$-th root of unity, and that the Galois group of $L/K$ is cyclic, isomorphic to $\mathbb{Z}/n\mathbb{Z}$.
Then there exists $b \in L^\times$ such that $L = K(b)$ and $b^n \in K^\times$. In other words, we have $L = K(a^{1/n})$ for some $a \in K^\times$.

For a standard proof, which does not involve representation theory one can see for instance [40, VIII, Th. 6.2]. The proof below is a bit longer, but it is quite easy to understand conceptually, and it shows another instance of applying representation theory to understand a naturally given representation of a group in order to solve a problem (as we saw in the first proof of Burnside’s Irreducibility criterion in Section 2.7.3 and as we will see also in Section 4.7.3).

**Sketch of proof.** We denote by $G$ the Galois group of $L$ over $K$, and by $\xi \in K^\times$ a primitive $n$-th root of unity. The first step is to note that it is enough to find an element $b \in L^\times$ such that $\sigma(b) = \xi b$, where $\sigma \in G$ is a generator of the cyclic group $G$. Indeed, one then finds that $\sigma(b^n) = b^n$, and since $G$ is generated by $\sigma$, that $b^n \in L^G = K$ (by Galois theory). Then we get $K \subset K(b) \subset L$, and it is elementary to show that $[K(b) : K] = n = [L : K]$, and hence deduce that $L = K(b)$, as claimed.

To find this element $b$, we observe that the condition $\sigma(b) = \xi b$, and the fact that $\xi \in K$, imply in particular that the one-dimensional subspace $Kb \subset L$ is a (one-dimensional) subrepresentation of the $K$-representation of $G$ on $L$ given by $\sigma \cdot x = \sigma(x)$. It is therefore natural (independently of knowing where this will lead us...) to attempt to understand this representation.

In fact it is very well understood: the normal basis theorem (see, e.g., [40, VIII, §13], and note that it applies to any finite Galois extension, not only to cyclic ones) implies that $L$ is isomorphic, as a representation of $G$ over $K$, to the left-regular representation $\lambda_G$ on $V = C_K(G)$ (see Exercise 4.5.5). Precisely, there exists $y \in L^\times$ such that $(\tau(y))_{\tau \in G}$ is a $K$-basis of $L$, and if we define

$$
\Phi : \begin{cases}
L & \longrightarrow V \\
x & \longrightarrow \varphi_x
\end{cases}
$$

by the condition that

$$
x = \sum_{\tau \in G} \varphi_x(\tau) \tau(y),
$$

one checks that the $K$-linear isomorphism $\Phi$ intertwines the action of $G$ on $L$ and $\lambda_G$.

Since $p \nmid n = |G|$, we have a decomposition

$$
V = \bigoplus_{\chi} K\chi,
$$

where $\chi$ runs over all characters of $G$ with values in an algebraic closure $\bar{K}$ of $K$.

Indeed, since $G \simeq \mathbb{Z}/n\mathbb{Z}$, all such characters have values in the group of $n$-th roots of unity, which is contained in $K$, and therefore can be seen as elements of $C_K(G)$. Since they are linearly independent, and there are $n$ characters, we obtain this decomposition although $K$ is not algebraically closed.

We observed that to find an element $b$ with $\sigma(b) = \xi b$, we must look among the generators of subrepresentations of $L$. This means that $b$ must correspond to a character $\chi$ by the isomorphism $\Phi$. But for such a $\chi$, we get

$$
\lambda_G(\sigma)(\chi) = \chi(\sigma)^{-1}\chi
$$

(because $\chi$ spans the $\chi^{-1}$-isotypic component of the left-regular representation). So the question is whether we can find $\chi$ such that $\chi(\sigma) = \xi^{-1}$. This is certainly
the case since $G$ is cyclic of order $n$ generated by $\sigma$ (see the proof of Theorem 4.5.2 (2) or Remark 4.5.3). □
